IODOTAN.

A preparation in which Iodine is combined with an organic acid, it is thereby rendered more readily absorbed than ordinarily and at the same time is deprived of its staining properties. Its use is indicated in all cases where Iodine is externally applied.

Yorkshire, and N. Midland V.A.

A COMBINED Meeting of the Yorkshire and North Midland Veterinary Association will be held at the Town Hall, Sheffield, on July 18th, at 11-30 a.m. An Address will be given on "The Present-day Veterinary Surgeon and his Successor," by Principal O. C. Bradley, Edinburgh.

Royal (Dick) Veterinary College, Edinburgh.

THE Board of Management is about to proceed to the appointment of a Professor of Pathology and Bacteriology.

Applicants must be Members of the Royal College of Veterinary Surgeons.

Letters of application accompanied by 15 copies of recent testimonials (if any) must be lodged, on or before Wednesday, August 27th, with THE PRINCIPAL, from whom particulars of the appointment may be obtained.

Practice or Partnership

WANTED, a country practice averaging about £600 per annum, or partnership in larger practice. Capital at command: references exchanged. Address, 1071 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

QUALIFIED, for mixed practice in South Midlands, state age, references, and full particulars. Address 1072. V.R., 20 Fulham Road, London, S.W.

Assistant or Manager

M.R.C.V.S., married, wants assistantship in good-class practice, or would manage branch. Large experience and excellent testimonials. Absolutely steady and reliable. Address, 1077 V.R., 20 Fulham Road, S.W.

Assistant Wanted

FOR busy practice (principally horse and dog). Recent graduate preferred. State age and salary required and give references. Address, 1078 V.R., 20 Fulham Road, London, S.W.

Wanted at Once

QUALIFIED assistant or, preferably, partner to manage flourishing veterinary practice in Scotland. Small capital required. Age, references, terms and photo to 1079 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

QUALIFIED, with a few years experience, for mixed country work. Interest in business given to a suitable man. State age, references and salary, living out, to 6107 V.R., 20 Fulham Road, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: In bottles, 6d. per dose; minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad), 1s. per dose.

G. H. PICKWELL, M.R.C.V.S.

Locum:

48A Kinnerton Street,
Knightsbridge, S.W.

Assistant Wanted

QUALIFIED, at once, for town and country practice, must be gentlemanly, steady, and well up in horse, dog, and cattle practice. Sign usual bond, state age, references, salary required to live out and all particulars to 1073 V.R., 20 Fulham Road, London, S.W.

Qualified Assistant

WANTED for wide and very lucrative country practice (including inspectorship) and with the intention of purchasing within 12 months. Must be good operator, castrate standing, etc., well up in parturition, and energetic. Splendid premises, all conveniences. Applicant must have capital and sign bond. Address, 1076 V.R., 20 Fulham Road, S.W.

To Veterinary Surgeons

WANTED, a gentleman who is fully qualified, experienced and reliable, to take charge of a country practice, with a view to a partnership. State age, last two appointments, how long in each, and remuneration required. Address, "Beta," c/o J. W. Vickers & Co. Ltd. 5 Nicholas Lane, E.C.

Assistant Wanted.

QUALIFIED, at once, for practice (chiefly colliery) in North of England. Permanency for suitable man. Write stating salary wanted, references, etc. Sign usual bond. Address, 1075 V.R., 20 Fulham Road, London, S.W.

Locum Wanted.

FROM 8th inst. for about a fortnight. State terms. Address, W. M. Jackson, Strathmore Road, Hamilton.

Locum.

QUALIFIED, experienced, practical, reliable; total abstainer; disengaged all July. Good references. Address, 7107 V.R., 20 Fulham Road, London, S.W.

Wanted

IN the first or second week of August, a qualified veterinary surgeon for a few weeks, in West-end London, practice. State age, where last employed and salary expected. Address, 8107 V.R., 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1304.

JULY 5, 1913.

VOL. XXVI.

VETERINARY LITERATURE.

No reader of the leading medical journals can fail to notice that the output of books by medical men is relatively much larger than our own. Naturally there are very many more works on particular diseases or classes of diseases; for medical practice, especially, perhaps, upon its surgical side, is more highly specialised than veterinary. But there is also a very large number of handbooks upon general medicine, surgery, and pathology—so many, in fact, that it is difficult to think that the majority can have any great circulation. It may be, of course, that medical men are more generally studious than we are. Or it may be that their profession holds a larger proportion of men rich enough to indulge in authorship as a hobby. The latter hypothesis would explain both the output of books and the fact that so many attain a sequence of editions.

Our own literature still shows room for improvement; but it is incomparably richer now than a quarter of a century ago. Many of us can remember the time when our stock of books was meagre in the extreme; but, among some superfluous works, we now have many really good ones. It is true that some of the best, such as the standard works of Chauveau and Neumann, are translations. But they are available to English readers; and their number is increasing every year.

There are still many gaps in our literature that might be filled, if only the right men would undertake the work. There are special diseases well worth separate treatment—for instance, now that bovine tuberculosis is being fairly taken up by the State, it surely deserves to be made the subject of an English work comparable to the recent German one of Ostertag. Of wider subjects, we have room for a full manual of toxicological botany—there is a first-class American work upon the subject, but one devoted to the flora of the British Isles would be preferable. There is room, too, for an authoritative text book upon forensic veterinary medicine and surgery—such works exist upon the Continent, but the subject demands separate treatment for each country. We could point to other such lacunae, but in most instances they could only be satisfactorily filled by men having special knowledge, and in some—as in the two last we have quoted—collaboration from outside the profession would be advisable.

PYELO-NEPHRITIS IN A FOAL.

In April last I was called to a valuable thoroughbred foal a few weeks old, whose dam was dead, and which had been brought away from the stud-farm where it had been foaled. It had to be taken in a cart from the railway station and next day was unable to get up, was suffering from profuse diarrhoea and was lame on the off hind leg. On examining the navel it was found to be still open and pus could be pressed out of the orifice, though no urine escaped from it when the foal urinated. Evidently it was a case of navel-ill.

The foal readily took from a bowl, milk and eggs beaten up with it. The diarrhoea was controlled by bismuth hæmatoxylin and resorcin.

Nuclein was given hypodermically, and the navel orifice was daily syringed out with a strong solution of chinosol. The stifle and the hock of the off hind leg were swollen and the foal was very lame on that leg. Subsequently the elbow of the near fore leg became swollen and hot and no weight could be put on the limb. However, none of the articulations suppurated, and in the course of a month the foal had, to all appearance, made a complete recovery, and was turned out to grass every day, where it galloped about apparently in perfect health. It now took crushed oats and hay, as well as milk. The navel was dry and painless to pressure.

This satisfactory condition lasted about ten days when swellings were noticed about the head, breast and abdomen; in a day or two food was refused, a violent attack of colic seized the little patient and it died. While the colicky pains were severe I passed a catheter and withdrew about a quart of yellowish urine of a high specific gravity but fairly clear.

On making a post-mortem examination the urachus was found to be greatly thickened, inflamed and hæmorrhagic, the bladder was empty, its walls thick and the mucous membrane swollen, pulpy and very red. The kidneys were greatly enlarged and in each the pelvis was distended by muco-pus, while the kidney tissue was flabby and friable, and it was difficult to distinguish between cortex and medulla.

A rather disappointing climax to what appeared to be a pretty successful case.

W. R. DAVIS.

UNUSUAL SUSCEPTIBILITY TO COCAINE.

A brown gelding, aged 8, and 14.1 hands high, was brought into the College to undergo Plantar neurectomy; 5 c.c. of a solution of Cocaine hydrochloride dissolved in equal quantities of water and Adrenaline chloride (1 in 1,000), were injected over the site of the high operation, half over the inside, and half over the outside nerve. The solution contained two and a half grains of Cocaine. A few minutes later the horse became restless, and began to sweat very profusely. There was marked trembling, slight twitching of the muscles of the hind-quarters, and some unsteadiness of gait. The animal was somewhat hyperæsthetic to touch, etc. Respirations were short, hurried, and to a large extent abdominal. Temperature was 101° F. Pulse was 50 to begin with, hard and strong, later it dropped to 40 and was somewhat irregular. After a while, the nervousness subsiding somewhat, the operation was proceeded with, in the standing position, and was successfully carried out, being marked by no untoward incident. The symptoms gradually disappeared within half-an-hour. The animal was rubbed down, dried, and afterwards discharged. He was in good condition and suffered from no obvious disease, likely to render him unusually susceptible to the action of the drug. There can be no question as to the Cocaine not getting into the blood-stream, because (1) there was no flow of blood on the insertion of the needle, and (2) its local action was perfect, no sensation being present. The animal was of a nervous disposition and it might be said that the symptoms were due to the handling associated with the injection of the Cocaine. This is negated by the fact that although subjected to similar handling during the operation, the symptoms did not recur.

EMPIRICAL THERAPEUTICS.

In Ireland, as elsewhere, one comes across many and wonderful "cures." For many years I was a Scoffer, but latterly I have been an interested observer and listener. I have come to the conclusion that there is an odd grain of wheat amongst the chaff. I would suggest that veterinary surgeons could have a worse pastime than trying to extract the "grains of wheat." I will give a couple of "cures" which may interest practitioners, helminthologists and biologists.

Tobacco is used as such, and also as a widely used proprietary article with a fancy name, for cattle known as "piners"; and cattle suffering from chronic diarrhœa. I have ample proof that the average "piner" in Ireland is a beast which shows no sign of disease by ordinary post mortem methods—but that the disease is caused by a minute strongylus well known to veterinary surgeons.

These "piners" mostly suffer from chronic diarrhœa, but a percentage do not show any digestive derangement. "Cases" are found on low-lying farms, or on farms bordering on lakes, rivers or marshes, or in cattle that have been fed on flooded hay. It is usually supposed that the complaint is beyond the skill of the ordinary veterinary surgeon—I have recently had the privilege of investigating two cases.

Case I. A pure bred Shorthorn Heifer had been unthrifty all winter with occasional diarrhœa; various remedies had been used, but the animal went away to a skeleton, scarcely able to walk. The farmer used the proprietary article, which he describes as mostly made up of tobacco; its effect was marvellous. The animal began to improve at once at time of writing she is fit for beef.

Case II. A two-year-old cross-bred bullock had been suffering from diarrhœa on and off for two months, many doses to stop the purging had been tried, but the animal gradually got thinner and weaker. A quarter pound of black cut cavendish tobacco was boiled with two quarts of water, and divided into three parts—one-third was given each day for three successive days—the diarrhœa gradually improved, and a week after the first dose the faeces were normal. The animal was carefully fed for a month or so, when it was sent to grass. At time of writing he is as good a beast as one could wish to see.

It will I think be agreed that the therapeutic value of tobacco is worthy of some study. There is no reason why we should sit with our arms folded and scoff at proprietary articles, whilst the owner of the latter makes himself rich at our expense.

Stagnant Water. I have heard from time to time of cattle being cured while suffering from redwater, with stagnant water, or stagnant beer; rotten beer has long since been regarded by some people as a sure cure.

I had the opportunity of verifying one case, a young three-year-old stripper cow was apparently in the last stages of redwater, looking very miserable, with sunken eyes—a case in which those experienced with the disease gave an unfavourable prognosis. This animal was driven into a field in which there was a tub of water. The water had been in the tub for at least two weeks, there was green slime and a bad smell present. The cow was thirsty and the day warm, so she drank most of the water. Next morning the urine had cleared considerably—on second day it was quite clear; the cow made a good recovery. I have sufficient collateral evidence to convince me that stagnant fluids are of great benefit in the treatment of this disease.

Note. The piroplasma of Redwater would, I suppose, be called animalculæ by common people. Biologists would probably agree that the fluids evolved by the animalculæ in the stagnant water might have some toxic effect on the piroplasms in the red blood corpuscles. The time may not be far distant when all kinds of animal parasites will be dislodged by the effete material of parasites of like

nature. The depraved appetite noticed in horses and dogs suffering from intestinal worms may have more in it than appears at first sight. It is just possible that the patients are in search of nature's antidote in the form of animalculæ and their excretions.

J. G.

ABSTRACTS FROM FOREIGN JOURNALS.

THE INFLUENCE OF THE PINEAL GLAND UPON THE GENITAL ORGANS.

Grigorin Cristea reports (*Münchener Mediz. Wochenschr.*) the results of his observations upon young cocks, from which he successfully removed the pineal gland. He operated upon thirteen birds, and twelve of these remained alive for seven months.

The observations showed that there is a close connection between the pineal gland and the genital organs, which can probably be attributed to the action of the internal secretion of the pineal gland. The cocks operated upon showed a striking arrest of development in the genital characteristics of the comb, wattles, spurs, voice, etc.; and the growth of the feathers was also decidedly slower than in the case of control birds which had not been subjected to operation.

The appetite and the bodily development were not visibly prejudiced by the operation, despite the fact that the birds showed marked apathy and loss of interest in their surroundings. Examination of the testes showed a pronounced atrophy in the case of the operated birds, which testified to a direct influence upon the testes of the removal of the pineal gland.—(*Münchener Tier. Woch.*)

THE QUESTION OF "PATERNAL" TUBERCULOSIS.

Nestor and Valsanu record (*Münchener Mediz. Woch.*) experiments they have made to determine whether an hereditary transmission of tuberculosis from father to offspring takes place. They subjected male rabbits and guinea-pigs to subcutaneous, intravenous, and *intra-testicular* injections of tubercle bacilli of bovine origin, and then coupled the males so treated with healthy females. In so doing, they were careful to exclude the possibility of tubercle bacilli and suppuration from the site of injection. The result of the experiments has led the authors to the conclusion that a direct transmission of tuberculosis from father to offspring by the hereditary route does *not* take place.—(*Münchener Tier. Woch.*)

BASEDOW'S DISEASE (EXOPTHALMIC GOITRE) IN THE DOG.

Hebrant and Antoine record a case of this rare condition. They have had charge of the clinique for small animals at the Belgian Veterinary School for nearly fifteen years, and during that period this is only the third time they have encountered the disease. Moreover, the two preceding cases were only very slightly marked ones. Four other cases

have been recorded in the dog by Jewsejenko, Lellmann, Sonnenberg, and Albrecht; and of these Albrecht's case is quite a characteristic one.

The subject of the present note was a male collie, three or four years old, and very plump in condition. He had already been in the infirmary, some months before, for symptoms similar to those about to be described, but after being kept quiet for a few days, he had recovered to the extent of being able to return home almost cured. This short period of treatment did not enable the authors to arrive at a precise diagnosis at that time. Diagnosis was rendered more easy, however, when the animal returned presenting symptoms identical with the former ones, only more accentuated.

When admitted, the dog showed very marked exophthalmia of both eyes, the left eye being a little more severely affected than the right. In addition to the abnormal projection of the eyeballs, the conjunctivæ were very red; and that of the left eye showed a fairly large ecchymosis, probably traumatic in origin. Close observation showed that convergence of the optic axes was difficult if not impossible, which might be due to a slight paralysis of the internal straight muscles of the eyes. The eyeballs themselves showed some difficulty in movement, there was therefore a slight ophthalmoplegia.

The history (from a professional colleague) was that the ocular symptoms had commenced by a slight engorgement of the temporo-maxillary region, with difficulty in closing the mouth. Then a little palpebral œdema had followed, and then protrusion of the eyeballs.

The owner's account was that the dog had for a long time been very sensitive and impressionable; he was changeable and often agitated in behaviour. He was nervous and distrustful towards all that surrounded him, and could only be approached and examined with great difficulty. He also showed muscular tremors, which were especially localised to the thighs and abdomen. These could not be ascribed to fear, for they were seen when the animal fancied himself alone and unobserved.

The pulse was regular, beating 120 to the minute; its artery was well filled, and its pulsation was ample. There was, however, no hypertrophy of the heart. This tachycardia was accentuated by movement, fatigue, or excitement.

The respiration was accelerated, but actual dyspnea was not shown.

The dog ate well, but showed perversion of appetite. Finally, there was a very slight diffuse hypertrophy of the left thyroid body, without appreciable cystic degeneration.

The authors diagnosed Basedow's disease. They would have advised operation (partial thyroidectomy or exothyropexy), but eight days elapsed before they were able to propose this course to the owner. During that time, under treatment by iodides, the exophthalmia retrogressed so much that the dog appeared recovered, and he was then taken home by the owner. These intermittences and apparent recoveries are usual in the early stages of Basedow's disease, but they are followed by recurrences of a permanent nature.

Less than a month after his discharge from the infirmary, the dog was brought back on account of grave ocular symptoms, compromising the eyesight. Each cornea showed a non-perforating ulcer; while both the crystalline lenses were opaque. The animal could no longer see. The authors regarded these lesions as the secondary result of the passive congestion of the eyeballs which had accompanied the exophthalmia a few weeks before.

The animal had retained all the previously described symptoms of the disease—tachycardia, very great sensitiveness, tremors, and slight hypertrophy of the thyroids. The exophthalmia alone had not yet re-appeared.

The authors instituted their usual treatment for corneal ulceration. Convulsions appeared, however; and these, proving refractory to treatment, soon became continuous and caused death within two days. The authors think that an abnormal secretion from the diseased thyroid had produced this effect, by impregnating the nervous centres and thus first causing the extreme sensitiveness, and finally the convulsions.

Post-mortem, the nervous centres showed no appreciable alterations; and there were no lesions in any of the other organs, except the thyroid bodies. These were hypertrophied, and, although firm to the touch, were gelatinous in aspect. Microscopical examination of them yielded no very particular results. The thyroid appeared with its usual structure, showing very voluminous thyroidal vesicles, with an epithelial lining more flattened than is normal. The blood vessels were well marked and dilated. A typical parathyroid existed at the surface of each thyroid, and two very reduced parathyroids in the thickness of the organ. In all sections they examined, the authors failed to find the "lymphatic islands" which have been regarded in human pathology as the essential cause of Basedow's disease.—(*Annales de Méd. Vét.*)

W. R. C.

LIVERPOOL UNIVERSITY VETERINARY MEDICAL SOCIETY.

A meeting was held on May 30th: There were present Messrs. J. P. Heyes, President; E. J. Burndred, G. H. Locke, W. J. Fletcher, J. W. Brittlebank, E. H. Stent, J. Share-Jones, R. F. Watson, Wm. Woods, F. S. Warburton, J. B. Wolstenholme, T. Dobie, E. F. Wood, F. A. Ball, Hy. Holdroyd, H. G. Hewetson, H. Sumner. Visitors: Messrs. F. C. Lewis, T. G. Millington, A. M. Munro. A demonstration was given by Prof. Beattie bearing on the Tuberculosis Order, 1913.

PROF. BEATTIE: Mr. President and Gentlemen,—In the first place I want to thank you for the opportunity you have extended to me of giving this demonstration, because I think at the present day something more drastic is needed in regard to the examination of milk, and I feel that the suggested examination by microscopical methods only is a definitely retrograde step.

After a prolonged experience I am convinced that the inoculation method is the only one by which we can accurately determine the presence of tuberculosis in milk. This I wish to demonstrate, and I hope to prove my case to your satisfaction.

A specimen of milk recently came before us taken from a cow which was regarded by the veterinary inspector as a suspicious case of tuberculosis. We examined it microscopically, and we found acid-fast bacilli resembling the bacillus of tuberculosis. I was not satisfied that it was bacillus tuberculosis, but the resemblance was so close that I could not give a definite opinion, and other observers of considerable experience thought it was B. tuberculosis, but by a series of inoculations we found that the animals showed not the least sign of tuberculosis.

The next case is, perhaps, more interesting. The milk contained acid-fast bacilli, and the inoculated animal showed an enlarged gland with cheesy pus. This pus contained large numbers of acid-fast bacilli, but after careful investigation of this organism we found that it was not B. tuberculosis; as a matter of fact it grows on ordinary agar media in 24 hours, and presents other features which are quite unlike B. tuberculosis. From the microscopical specimens which I show, I think anyone will admit it would be extremely difficult to distinguish it from the true tuberculosis bacillus.

Here, then, we have two cases coming to the laboratory within a month in the ordinary routine of our work, both giving sufficient evidence, I think, that trusting microscopic examination only there is great liability to err.

In my opinion any authority which dispenses with the inoculation method is doing a very dangerous thing, going back to the old status again when tuberculous milk will undoubtedly be sold, and the public will be under the false illusion that its milk supply is being carefully guarded from infection.

Another point I want to illustrate is the method of examination. I consider that the examination is unsatisfactory unless a considerable quantity, at least 100 c.c. is used, and that quantity centrifuged and the deposit from it examined microscopically and inoculated into animals. I show you two specimens which we obtained from a shop to-day, and you see in the centrifuged sample the deposit which actually contains blood, and this in spite of the strict precautions we have in Liverpool.

There is another point not sufficiently emphasised—I mean faecal or dirt contamination. I am one of the heretics who believe infantile diarrhoea is largely due to contamination of our food supplies with B. coli and the ordinary organisms, and not necessarily to some special bacillus; and our aim should be not merely to get rid of B. tuberculosis in our milk, but also to get rid of the dirt with its associated bacteria.

More stress ought to be laid upon examination for, particularly, B. coli as an indication of want of cleanliness in the milking process. In fact I will go the length of saying that it is equally, if not more important to get rid of dirt in our milk than to get rid of B. tuberculosis.

There is so much tendency in these days of specialisation for those in authority to concentrate on one thing and leave others alone. These dirt organisms should be energetically dealt with, and if we are to deal effectually with the tuberculosis problem I am convinced that a fatal error will be committed if the method of microscopical examination is substituted for the inoculation procedure: or even if the microscopical method is given much prominence.

(Prof. Beattie with the aid of microscopes showed different specimens of tubercle and other acid-fast bacilli in milk).

MR. WOLSTENHOLME asked Prof. Beattie what proportion of acid-fast bacilli he found in milk which turned out not to be tuberculous.

Prof. BEATTIE: In regard to the proportion of acid-fast bacilli, I am afraid I cannot give you the proportion. As I have pointed out, during microscopical examination we had two cases of this kind which were definitely proved not to be true tuberculosis, and during the same period we had not more than four cases of true tubercle. Even the most enthusiastic supporters of the microscopical method admit 10 per cent. of failures, and why should we adopt a method which is erroneous to that extent.

Mr. WOLSTENHOLME: Of course the point of my question will be quite apparent. There must be some methods or mode of procedure to more or less relieve the minds of the veterinary surgeons as to whether a certain cow is giving milk containing bacilli of tuberculosis. Should the examination for acid-fast bacilli be unsuccessful there would be another method. Send every sample of milk of which we had the least suspicion to a public institution and wait whilst they make an examination for acid-fast bacilli in the sample. Wait five or six weeks until this method I am now sketching is complete, until distinct proof has been obtained by means of inoculation. My opinion is that preliminary examination is a very good thing, and somebody who is fairly capable should examine, and if any acid-fast bacilli are found, then submit the sample to the institution for experiment. We cannot say definitely whether they are non-tubercular or tubercular in these examinations.

From one point of view it would be almost better to assume that any milk which gives acid-fast bacilli is tuberculous, and at once condemn the cow. From my point of view I would condemn the cow straightway without any further examination. There is a difference between a cow being destroyed and parts used which are fit for food, and the risk of human life, from going on using milk for five or six weeks which is definitely giving acid-fast bacilli. The former method is far preferable. A rough method to apply to further tests is fairly practicable.

Prof. BEATTIE: I quite agree with what has been said in relation to that. If you are going to destroy every cow in which you find acid-fast bacilli, I quite agree that you are helping to get rid of tuberculosis, but you have got to take into consideration that if you adopt the microscopical method alone, you fail to detect 10 per cent. of the cases, and you are still supplying tuberculous milk. It seems to me a much better plan to isolate the cow in which you find acid-fast bacilli for five or six weeks, until you have got your report. If not tuberculous, the farmer or dairyman should be compensated for the loss he has sustained in not being able to sell his milk. If it is tuberculous the animal could be slaughtered and, of course, he would have no claim for compensation.

Mr. WOLSTENHOLME: Another practical solution. Supposing the law empowered the use of tuberculin test in the case of every cow producing acid-fast bacilli.

Prof. BEATTIE: Again I am afraid I could not agree that this would be satisfactory for the tuberculosis indicated might be in any part of the body and the udder be quite free.

Mr. BURNDRED: Do you consider that these acid fast bacilli are present in milk drawn from the udder or that the milk is contaminated later.

Prof. BEATTIE: Well, my view is that the acid-fast bacilli get in as a result of contamination, but one cannot deny the possibility of the bacilli coming from the udder.

Mr. BRITTLEBANK: I should like to ask Prof. Beattie under what conditions samples of milk examined have been collected. Whether in collecting samples a system of cleaning the udder or the teat is adopted? I must admit the extreme interest of what has been said. It was our experience in the early days to find these acid-

fast bacilli which were not tubercle bacilli. In recent years, so far as my own cases are concerned, we never had a case such as reported here. The method always adopted in the collection from the suspicious udder is first of all cleanliness of the teat. Scientific cleanliness is not always possible. Then a considerable quantity of milk contained in the udder is rejected before proceeding to take sample: then we have found we did not get these conflicting acid-fast bacilli. So far as the 10 per cent. of failure is concerned, Professor Delépine, I think, last year, found his microscopic methods accurate in 90 per cent. cases.

Some years experience of the practice of this special method of collection of the milk helped very considerably from an administrative point of view. One knows perfectly well it would be insane to do away with inoculation tests. The difficulty of asking a man to isolate a cow for five or six weeks is great. The natural result—and what oftener followed—is that the cow lost condition from being put away after being used to the society of other animals.

So far as my practical experience takes me, having done a considerable number of bacteriological examinations of milk myself, I agree that having found acid-fast bacilli, I urge the farmer to get on with killing his cow, and in a large series of post-mortems we have never been wrong. It may be that this is due to the careful work of Prof. Delépine, and I want to pay every tribute to him for the work which he has done. There is no doubt that microscopical examinations have helped us enormously in carrying on administrative work. Those 10 per cent. of cases which Prof. Beattie referred to should be provided for by the Tuberculosis Order.

We do not presume men in everyday practice will find anything like even 50 per cent. or 60 per cent. cases to be tubercular, and if there is any doubt we should go further and submit the case for further bacteriological examination.

Prof. BEATTIE: I am in no way responsible for the method of collecting samples, and I confess I am not satisfied with the methods we adopt. I agree with the speaker that it is the extreme care taken by my friend Prof. Delépine which gives him 90 per cent. of success, and if we were having the work done by such careful and experienced men, perhaps my views would be modified, but the work is to be done by many people who will not take that care, and the result will be that we shall have numbers of cases of tuberculosis missed altogether.

Mr. BRITTLEBANK: Tubercle bacilli can be found in mixed milks. In early days when many cases were closely inspected the results were very considerable.

Prof. BEATTIE: With regard to the question of isolation I do not suggest that the farmer or the dairyman should isolate, but that the local authorities should take charge of the cow. They should take it away altogether. It is their duty to do so, and to remove the temptation to the farmer to use the milk when nobody is looking.

Mr. FLETCHER: Would Prof. Beattie tell us whether we would be more likely to find tubercular bacilli in the first milk, the second, or the last stripping. In Scotland, I believe, they are in favour of the middle milk, but our people in Manchester are in favour—strongly in favour—of the stripping.

Prof. BEATTIE: I have not considered the question, but I incline to the view that the last milk is more likely.

Mr. BURNDRED: In one of your examinations at Sheffield a sample of milk was taken and you certified the presence of one acid-fast bacillus, but would go no further. We were very suspicious of the cow, and it was isolated for just over three weeks, when your results of the inoculation tests were sent in as being non-tuberculous. The owner came down to the Health Office, and I persuaded him to bring it down to the

abattoir, have it slaughtered under his own hands, and sell to a butcher and take the risk of it passing muster. The best explanation that can be found for this sample of milk containing very few bacilli is that, at that time probably what few there were had been taken out and put on the slide.

Prof. BEATTIE: The probable explanation is that in the milk sent there were no *B. tuberculosis*. There may not have been sufficient pressure on the tuberculous area to cause any *B. tuberculosis* to be ejected. I feel very strongly that the clinical side must be associated with the bacteriological, and if the clinician is fairly sure of tuberculosis, and acid-fast bacilli are found, then I would have no hesitation in slaughtering the cow.

Mr. FLETCHER: In the Order the word discharges was used. It does not say exactly what the discharges are. They may be discharges from the lungs by coughing—a discharge of mucus, or the discharge from diarrhoea. I would like to ask whilst mentioning diarrhoea—as it is now common knowledge that you get tuberculosis of the bowels with diarrhoea—whether or not it should be considered suspicious of that disease.

The PRESIDENT: The question put by Mr. Fletcher has been in my mind and I would like some information from Prof. Beattie. One encounters many cases which give rise to a suspicion of tuberculosis, one can easily perceive pathological organisms being responsible for such conditions of the lungs or bowels. If the animal is in an advanced state of disease, one would rely upon the tuberculin test. One would like to know how to proceed to satisfy himself that he was dealing with tuberculous or other lesions. It is a difficulty I have experienced and I ask now for information as to whether one ought to look for a discharge such as Mr. Fletcher has referred to would justify a positive or negative opinion.

Prof. BEATTIE: In relation to these matters I should say if you have got an advanced state of tuberculosis in the intestine or in the udder, you should search the faeces and the milk for *B. tuberculosis*.

Mr. SUMNER, in proposing a vote of thanks to Prof. Beattie, said: I think we all acknowledge our gratitude to him for his excellent address to-day. Although it is so hot and veterinary surgeons in this season are very busy indeed, it is evidence that we all take great interest in the subject by turning up in such goodly numbers to-day. I have no doubt a great many members of this Society would like to have been present who are unavoidably absent. Our Secretary had to go away, and he expressed his great regret.

I am perfectly certain I am voicing the opinion of the audience when I say we are greatly indebted to Prof. Beattie for the very lucid demonstration and his answers to the questions that have been knotty problems for some of us.

The PRESIDENT: I am asked to say that Prof. Beattie will be very glad to take the members over to the laboratory and show them several of the processes.

Prof. BEATTIE: I simply thank you very much. I really need no thanks. My feelings are very strong on this subject. I am extremely grateful for the critical questions put to me, and one has a pleasure in being cross-questioned so much. Then with regard to the invitation to visit the laboratory may I extend it further, and say that at any time any of the members come up to the laboratory, I will show you not only the method, but also the apparatus at work.

PRESIDENTIAL ADDRESS.

By Mr. J. P. HEYES, F.R.C.V.S., Wigan.

Gentlemen,—First let me say how pleased I am to find myself in the honoured position of President of the Society. I look upon it as a great privilege to be

selected to follow in the footsteps of such men who have adorned this chair—men who have in the face of many difficulties helped to make this Society a means of providing facilities for the scientific advancement of its members, such as are not excelled by any other Veterinary Medical Society.

It is my earnest hope that during my year of office I may see an ever-increasing desire on the part of our members to contribute to the success of our meetings by attending regularly and bringing such specimens or notes of cases as are likely to be of more than ordinary interest.

It may not be inopportune here to refer briefly to the opportunities that exist in connection with this Society for assisting practitioners in arriving at a correct diagnosis of such morbid conditions as require an exhaustive laboratory examination.

Those of us who try to put our knowledge of pathology or bacteriology into practice should make use of the laboratory to confirm or negative our opinions. It will interest the members of the profession in this district to know that a special course has been designed in the University to meet the requirements of veterinary inspectors under the Tuberculosis Order.

The value of association by members of our profession has never been exemplified to a greater extent than during the past few months. The coming of the Tuberculosis Order of 1913 caused veterinarians all over the country to seek counsel with each other, and the Veterinary Medical Societies were soon recognised as the best media for obtaining enlightenment as to the meaning of this very important Order. I don't think it is any exaggeration to say that it is one of the most important steps in connection with preventive medicine in the history of the veterinary profession.

Many of us have for years been racking our brains for an efficient and yet practicable means of eradicating tuberculosis from amongst the cattle of the country, and probably everyone who has given the matter much thought has conceived a plan for dealing with this disastrous disease. I think it will be generally admitted, however, that no course could be on the whole more likely to produce the desired result, and at the same time be more acceptable to the stockowner and the people of the country than this which has emanated from the Board of Agriculture this year.

I do not propose to address you at any great length to-day, because like many another man here, I am very very busy in practice. It is as far as I had got for this presidential address. Like lots of other men I have been going through points I had intended to go into at this meeting as I have driven through the country—speeches, political, professional, and otherwise, have been prepared for some time. The slaughter of all tuberculous cattle was recommended years ago by the then leaders of the profession, but it was recognised as practically impossible when it was discovered that such a large percentage of the cattle of this country was affected with tuberculosis. It is therefore obvious to all who had made investigations in the subject of tuberculosis that the best method of procedure was to slaughter all those clinically affected animals, as the greatest source of danger, and I take it the object of the framers of this Order is to slaughter clinically affected animals chiefly.

Now, the administration of this Order appears to be placed in the hands of veterinary surgeons and quite rightly, and the veterinary inspectors of the country have been very busy for many weeks getting into harness to try to do the work to the general satisfaction of those who employ them in the country, and I have no hesitation in saying the veterinary surgeons of the country will be quite equal to the task imposed upon them. I am perfectly certain that any man who has the privilege of being a veterinary inspector realises his responsibility.

It must be remembered that we are only now starting—only at the commencement of a period when we are trying to deal fairly and practically with the reduction of tuberculosis. As time goes on we shall acquire better means of diagnosing tuberculosis, and we shall be able to definitely say whether an animal is tuberculous or not. I am not so much concerned whether veterinary inspectors are able to carry out the work, I am concerned how the work is being done by veterinary inspectors—in fact, who the veterinary inspectors are going to be. Veterinary surgeons begin to ask themselves whether it is not the best course—now that so many diseases are scheduled under the Contagious Diseases Act, so many duties given over to veterinary surgeons, now that the public are clamouring for veterinary surgeons to inspect food and animals giving food, and assist medical men in the country—to consider the question of whole-time men for these appointments. This is work of very special line and work that men ought to devote a great deal of time to study.

Very good work has been demonstrated this afternoon by Prof. Beattie, work that requires very great care, and if we are to do ourselves credit in carrying out this work is it not our duty to support the appointment of whole-time men to do it? There is no insuperable difficulty of creating such appointments. There is not a staggering amount of cost involved, and I don't see why we as a profession ought not to voice our opinions and say we prefer that whole-time men should do this work, men who are in practice now. Veterinary inspectors may think it will be hard upon them and that they would be losing something. I venture to say they would gain something by closer inspection of animals. The services of veterinary surgeons will be requisitioned. I feel confident he will benefit in the end. Again, it is not fair to the veterinary surgeon engaged in practice who is not a veterinary inspector.

The diseases scheduled under the Contagious Diseases Acts call for the frequent visit of a veterinary inspector to all cowsheds and stables, over which he has supervision. I think I am not the first to say that certain veterinary surgeons do not care to have to compete with veterinary surgeons visiting the yards of their clients. In fact I remember a statement a very short time ago to the effect in connection with insurance.

Another way in which the usefulness of Veterinary Medical Societies have been evidenced lately has been the desire on the part of certain societies to fix charges for certain classes of work. I think we ought to consider it undignified as professional men to charge ridiculously low fees for some of the services that we are called upon to perform. It is often done, we must admit that there are men who only charge low fees and when they are supplanted, somebody has made a lower charge than they. That is an argument in favour of veterinary societies. Regarding the question of what shall be minimum fees for certain services, I do not see how you can tie a man down to these things, but in the legal profession there is a recognised standard of fees, and I do not think it would be out of place for us to fix a standard. It would assist in many ways, for instance insurance fees paid by insurance companies have been discussed by men of veterinary societies. We could say to the insurance companies, "Here is our fixed charge, these fees are fixed by the veterinary societies of the country." I do not propose to say anything further except to thank you again for inviting me to occupy the position of President this year. (Applause).

Mr. BRITTLEBANK. Mr. President and gentlemen,—In the first place may I congratulate you, as a fellow-member of this and of another Society such as this, on the position you occupy to-day. This Society will not only gain in prosperity, but in enthusiasm. I do not propose to enter into any political questions which you have raised; I hope for the present to confine my poli-

tical views to a narrow circle. I am concerned more particularly for the time being with the Society we have formed in the country—the National Association of Veterinary Inspectors—which we hope will meet with the support of all veterinary inspectors in whatever branch of work they may be concerned. This Association is absolutely non-militant, but has for the basis of its foundation the hope that by combination and discussion we may arrive at a uniform system of working and incidentally improve the positions of all veterinary officers, either whole or part-time, who are engaged in public work. We have a membership up-to-date approaching 200, and hope very soon to include every veterinary inspector. Whatever branch he is connected with, every man should be a member of that Association, and it will be an important factor in the history of the veterinary profession.

In so far as the President has referred to the Tuberculosis Order, it will be seen that he, like many of us regards the Order as a necessary preliminary to some legislative procedure of far-reaching character. How soon we can advance will largely depend upon the acumen and diligence with which this order is carried out by the veterinary profession.

Undoubtedly something was absolutely necessary, shall I say to co-ordinate throughout the country the efforts which are being made to deal with this the greatest scourge of the farm, and it must be admitted on all hands that the time was fully ripe for some measure, however limited its scope might be, to start this campaign for the reduction of Bovine Tuberculosis.

The Board of Agriculture in their legislation distinctly deal with two or three classes of Tuberculosis, and these which are notifiable are tuberculosis of the udder, tuberculosis with emaciation, and animals which have a discharge which is tuberculous. I take it that a cow coughing up tuberculous material, a cow with tuberculous discharge from intestine or uterus, or a discharging tuberculous joint would come into this category, so that, if the full resources of bacteriology were at our disposal the scope of action would be very wide.

I need not refer in detail, I think, to the various articles of the order if most of you will have read them. Article 2 requiring notification is the same as in any of the other orders made under the Diseases of Animals Acts, and Article 3 requires notification from the private practitioner who may be in attendance. The next section, or rather Article 4, is a far-reaching one, and provides for the inspection and examination of animals; and one aspect of this article I might refer to which is somewhat outside the general work of the average veterinary inspector. You will notice that the wording of the beginning says, "Where a local authority by reason of information received under the preceding articles or otherwise," and what I have in view is that there will be many local authorities who have mixed samples of milk examined for tuberculosis, and in the event of the source of such a sample being outside the area of that local authority—they would notify to the local authority concerned, the fact that a certain farm was sending tuberculous milk, it would then be necessary for the veterinary inspector of the local authority concerned to visit such a farm and arrive at a conclusion as to the particular animal or animals which are producing the infection, such inspection will have to be very carefully made for the authority notifying the infection will be certain to take control samples for further biological examination to see that the infection has been removed. On the other hand, those authorities who have the milk clauses will still send their own veterinary surgeon wherever the farm may be situated.

The clause particularly which is of some moment is Article 6, which deals with valuation for compensation. I do not want to criticise the Order, we are here to discuss it: criticism at this stage may have destructive

rather than constructive effect. In this compensation, as most people know, we see that there are two values required. The animal has to be valued first of all as a potentially healthy animal, and in the second case as a tuberculous one. The first valuation is comparatively simple. You take the animal as she stands, she may be in good condition, very likely in poor condition, and you make your valuation, not as what she was before she became in poor condition, but as she stands. The second valuation seems to me to be the most difficult, and as far as experience takes one, I would suggest you make the first valuation reasonably liberal, because if you make a mistake and the cow after a post-mortem is found not to be tuberculous, it is only fair that the owner should receive compensation, on a fairly liberal basis, plus the £1 which is provided for.

While making such valuation you may be suspicious that it is not tuberculosis alone which is responsible for the condition found and in such case you can, if applicable, make use of Section 2. Article 6, which is as follows: "In ascertaining the value of an animal, regard shall be had to any Act, Order, or regulation dealing with the scale or use of milk, milk products, or carcasses for human food."

It is perhaps somewhat unfortunate that it is legally established that there is money value attaching to tuberculous animals and the valuation of these animals, satisfactory alike to the owner and the local authority will not be easy to arrive at, but I have little doubt that the practical men concerned will not meet with difficulties which are insuperable. The only method I know of valuing such animal is to take her in the position that you see such animals in the large auction marts in the country, you see them in considerable numbers—animals which include mildly suspicious cases—brought by a class of individuals who fully recognise the financial risk they are running in the hope of getting one out of three passed, and practically reimbursing them with a certain amount of profit. This seems plain sailing enough, but take a case such as one commonly meets—a cow suffering from tuberculosis of the udder, clinical evidence that both lungs are affected, the cow is in excellent condition, in fact to the untrained eye she is a big healthy cow. As far as I am concerned I could not place any high value on such an animal, acting in the light of my experience, and an owner might, and no doubt would have a grievance. I have been asked to refer to the post-mortem assessment, but I do not really see any difficulty about this part of the Order, as under Article 8, the conditions are clearly laid down, and I think wisely so, for they leave no room for difference of opinion, which is something to be thankful for.

Certain points which have arisen recently, and which might be of some practical interest, dealing with a phase of our work, which has been made a good deal of. I think it has been the general impression among many veterinary surgeons that under this Order there would be a great amount of tuberculin testing necessary. As far as I am concerned, I do not see, under this Order, where the real necessity is for any extended use of the tuberculin test. In fact, as a matter of tactical procedure it is advisable for the veterinary inspector to refrain from testing as much as possible, at any rate at the outset. He should make it his mission to deal with the case from a clinical point of view, and in the case of milk, by bacteriological examination—or if necessary, biological examination, and it is certain that however skilful a man may be, it will be necessary in many cases to resort to the inoculation of the guinea pig.

There is, however, a class of case which will be met with in practice where an animal becomes emaciated from apparently very indefinite cause. These occur in no particular class of animal. The only marked evi-

dence which you have before you is wasting; examination of the lungs reveals little, palpation of the udder nothing. This is the class of case which it seems to me will require the application of the tuberculin test. There are many conditions which simulate tuberculosis and are produced by a variety of causes. Those particularly interested in dairy cattle will readily bear me out in this. Many a time one has found, particularly in newly purchased animals a cow which shows every symptom of tuberculosis—wastage, cough, capricious appetite, may be increased temperature, hide-bound starving appearance, and a fretted discharge from the genital passage. These cases under proper treatment as a rule do well, and when the cause is removed, which may be a small portion of decomposed cleansing, the animal gets well and into good condition again very rapidly.

Parasitic and other bacterial conditions producing similar symptoms, and in these cases, even though there may be a slightly elevated temperature, I do not hesitate to proceed to test with tuberculin and am not frightened of using a good big dose; 5 to 6 c.c. of tuberculin, I have frequently used, and with very satisfactory results. There must of course be a margin of discretion so far as elevated temperatures are concerned, and this must be left largely to the clinical acumen of the veterinary surgeon.

Another class of case in which tuberculin will be found useful; and indeed often necessary, is that class of cow which I may designate as old and worn out. They are frequently emaciated, but clinical examination reveals little. I suppose the law of the survival of the fittest holds good, for it is astonishing how free from disease many of these cows are at post-mortem.

I plead here for men to rely as far as possible on their own clinical judgment in regard to the Order. I am perfectly certain it is not intended by the Government that you should be confronted by insuperable obstacles in the way of smooth working of this Order. When difficulties arise you should exercise your ingenuity, without reference to outside people. That percentage of cases in which you find it impossible to find the tubercle bacilli in the milk microscopically, as Prof. Beattie has stated, will be met with, then I think your duty to the community and to the consumer would be to take a further sample and submit it to a biological test. I am also of the opinion that one should lay down a certain definite system for the purpose of examination of milk. Where you have suspicious evidence in an udder you should exclude practically all the milk that is in the cistern, and leave in the udder just as much milk as you think you will require—a matter of from four to six or eight ounces of milk for examination. You should go further, take hold of the suspicious quarter and massage it as much as ever you can, and you need not be particular about it. You may be told that the owner will object. Of course if you proceed to tell him that by collecting the sample in this manner you will be more likely to find the tubercle bacillus, a percentage might object, but so far as my experience takes me, I have yet to meet such a person, and indeed I would remind you that under the Order it is useless for the owner to object; there are provisions in Article 4, Sec. 2, 3, and 4 which amply protect the inspector. You may say that I lay a great deal of stress on this point. Naturally I do, when I have found after fairly extensive practical experience that if you want rapid results in the examination of milk you must deal with the last milk you can express from a suspected quarter or quarters.

There is one other point which I think of sufficient importance to refer to. I know many people think that if an owner notifies a case, and this case has been proved to be tuberculosis, as required by the Order, that the owner cannot slaughter such cow without the consent

of the authority. This is not so, it is clearly laid down in Article 10 (latter part) that the animal may be slaughtered at any time by the owner or person in charge. He would of course receive no compensation.

There are many other interesting features in this Order, but I fear, sir, that I have already sufficiently trespassed on your time and patience. The profession has had a great work placed in its hands, we must proceed warily and with discretion; nothing will be gained by undue haste, and I am confident that the veterinarian will justify the confidence placed in him, and so hasten the time when legislation may be put forward which will take us still further along the path to the goal we must all aim for, and that is complete eradication.

I thank you again, gentlemen, and you particularly, Mr. President, for asking me to open this discussion.

Mr. FLETCHER: I have very great pleasure in rising after Mr. Brittlebank to second the proposition of a hearty vote of thanks to our President for his address. There is a good deal of matter to think about. Mr. Brittlebank has referred to the most important parts I congratulate you upon your address, and I feel sure you will prove a very great acquisition to the Society.

Mr. BARKER, M.R.C.V.S., D.V.H., was unanimously elected a member of the Society on the proposition of Mr. Share-Jones.

Before the meeting dispersed a vote of condolence was passed to the relatives of the late Mr. Faulkner in their recent bereavement.

* As Diseased or Exposed to Infection

SOUTH DURHAM AND NORTH YORKSHIRE VETERINARY MEDICAL ASSOCIATION.

A meeting of the Sub-Committee appointed to consider the fees paid to veterinary inspectors, was held in the Imperial Hotel, Darlington, on Friday, May 9th, the President, Mr. W. Awde, Stockton-on-Tees, in the chair. There were also present Messrs. G. R. Dudgeon and T. T. Jack, Sunderland; J. M. Walker, West Hartlepool; S. Morton, Middlesborough; P. Snaith, Bishop Auckland; H. Peele, Durham; P. B. Riley, Barnard Castle; G. B. Holden, Scarborough; T. Wilkinson, Lanchester; W. N. Dobbing, C. G. Hill, and J. H. Taylor, Darlington.

The PRESIDENT stated that the meeting had been called to consider the fees which had been suggested by the Executive Committee of the Durham County Council and also to consider the Tuberculosis Order (1913).

The SECRETARY read Mr. Peele's letter, which stated that in accordance with the resolution passed at the meeting of the Association held on March 7th, he had brought the question of the fees payable to veterinary inspectors by the Durham County Council before the Executive Committee of that body. He had had some difficulty in convincing some of the members of that committee that any increase of fees was necessary, but he had received great help in the matter from a doctor who was on the committee, and this gentleman had helped him in putting the matter before the other

members, and thus pointing out to them how inadequate the present fees were.

The committee eventually recommended the following revision of fees, subject to the confirmation by the Council at their meeting in July. He had, however, received a promise that if the suggested fees were agreed upon that they should date as from the 1st April last.

SUGGESTED NEW SCALE OF FEES.

Anthrax.	Visit and inspection of single animal	...	10	6
	Microscopical examination: report and material to Board of Agriculture, etc.	...	10	6
	Examination of contact animals 1/- per head maximum	...	3	3 0
	Mileage 1/- per mile one way, or 1st Class rail fare	...		
Glanders.	Visit and inspection of single animal	...	10	6
	Inspection of contact animals 1/- per head maximum	...	3	3 0
	Mallein test up to four	...	2	2 0
	" after four—for each animal	...	5	0
	Mileage 1/- per mile one way or 1st Class rail fare. Cost of mallein should be refunded on producing voucher	...		
	Mileage for one journey only when applying the test	...		

Tuberculosis. Visit and inspection of single animal ...	10	6
Inspection of contact animals 1/- per head maximum ...	3	3 0
Microscopic examination of milk ...	10	6
Tuberculin test as in glanders		
Mileage, 1/- per mile one way or 1st Class fare		
Cost of Tuberculin should be refunded on producing voucher.		
Parasitic Mange in Horses. Visit and inspection of single animal ...	10	6
Microscopic examination when necessary ...	10	6
Examination of contact animals 1/- per head maximum ...	3	3 0
Mileage, 1/- per mile one way or 1st Class fare		
Sheep Scab. Visit and examination of flock of 125 ...	10	6
Visit and examination of flock over 125, 10/6 for each 125 to maximum ...	2	2 0
Microscopic examination when necessary ...	10	6
Mileage 1/- per mile one way or 1st Class fare.		
Mileage. In all cases to be 1/- per mile one way after first two miles.		

Miscellaneous.

Post-mortem examinations where duly authorised 21/- for Glanders, 10/6 any other disease. Attendance at markets, sales, etc., 10/6. Examination of single animal, or if a number 1/- per head, maximum £1 11 6. Telegrams, postage, etc., to be refunded.

Mr. DUDGEON thought that the Inspector ought to accept the proposed scale of fees, but thought that as regards mileage, 1/- per mile ought to be allowed from leaving home, and not only after one had gone two miles.

A general discussion then took place, most of those present taking part, and it was agreed that Mr. Peele should bring the question of mileage before the Executive Committee and request them to allow the mileage to be charged from leaving the place of business.

Mr. DUDGEON proposed that a hearty vote of thanks be given to Mr. Peele for the trouble he had taken in bringing the whole matter before the Executive Committee. He considered that the suggested scale of fees was satisfactory, and was a great improvement on what had previously existed.

The vote of thanks was seconded by Mr. Walker, supported by Mr. Snaith and carried unanimously.

Mr. PEELE thanked the members and said that he had only been too pleased to render the little service, and naturally he was very pleased with the result, as he had every confidence that the scale of fees would be confirmed by the Council at their July meeting.

Mr. HILL said that he had received a telephone message from Mr. Pratt, Chief Veterinary Inspector to the North Riding County Council, and he wished him to express his regret at not being able to be present at the meeting, as he had been called out to an urgent case. He wished him to tell the members that he had brought the question of fees before the Executive Committee of his County Council, and they had recommended that Veterinary Inspectors be allowed five shillings for the first hour and two shillings and sixpence for each subsequent hour. For applying the tuberculin test to not exceeding two animals £1 1s., with 5/- each for additional animal.

Mr. HILL said that he was afraid that was all the information he could give them.

The circular letter sent by Mr. Pratt to all the Inspectors in the North Riding was next referred to. From the wording of that letter it was understood that all samples of suspected milk were to be sent to Mr. Pratt for microscopical examination and on this matter

being discussed it was generally agreed that it would have been better had this matter been left in the hands of the Inspector engaged in the case, as in Durham.

Several of those present stated that they had got their microscopes put into proper order naturally thinking that they would have to make the necessary examination, and now were told that they were not allowed to do so.

Mr. AWDE thought that from his reading of the letter they would be allowed to make the necessary examination of milk and that it would have to be confirmed by Mr. Pratt.

It was agreed that the Secretary write to Mr. Pratt and inform him that "The Veterinary Inspectors present at this meeting enter their protest in not being allowed to make the microscopical examination of milk and are strongly of the opinion that each Inspector ought to be responsible for such examination.

The members subsequently had tea in the hotel.

A meeting was held in the Imperial Hotel, Darlington on Friday, June 20th. Owing to the unavoidable absence of the President the chair was occupied by one of the Vice-presidents, Mr. C. G. Hill, Darlington. There were also present Messrs. G. R. Dudgeon, Sunderland; W. H. Blackburn, South Hetton; J. M. Walker, West Hartlepool; S. E. Morton, Middlebro'; P. B. Riley, Barnard Castle; E. H. Pratt, Northallerton; G. E. Nash, Richmond; P. Snaith, Bishop Auckland; E. R. Gibson, Seaham Harbour; W. N. Dobbing, C. G. Hill, F. H. Sanderson, and J. H. Taylor, Darlington.

Visitors: Messrs. T. Wilkinson, T. T. Jack, Sunderland; G. A. Harrison, Stockton-on-Tees; and H. Hall, Northallerton.

A telegram was received from Mr. H. Peele regretting his inability to be present.

It was proposed by Mr. Gibson, seconded by Mr. Dobbing, and carried, that the minutes of the previous meeting as they appeared in *The Veterinary Record* be taken as read.

New Member.—Mr. F. H. SANDERSON, Darlington, was elected a member of the Association, on proposition of Mr. Snaith, seconded by Mr. Dobbing.

Mr. HILL, in welcoming Mr. Sanderson, said that he was very pleased he had become a member of the Association, and he hoped he would make an effort to attend the meetings, report interesting cases, and take part in the discussions.

Mr. SANDERSON thanked the members for electing him and said that he should certainly attend all the meeting he could, and help in any way he could to make the meetings a success.

Nominations.—Mr. T. T. JACK, Sunderland, proposed by Mr. Dudgeon, seconded by Mr. Gibson.

Mr. T. WILKINSON, Lancaster, proposed by Mr. Hill, seconded by Mr. Dudgeon.

Correspondence.—A letter was read from Mr. Wooldridge acknowledging the receipt of the affiliation fees from the Association to the N.V.A. and strongly urging all the members to join the N.V.A.

Letter from Mr. Noël Pillers, Hon. Sec. of the Northern Branch of the N.V.A. suggesting the words:

"A division of Northern Branch of the National Veterinary Medical Association," be placed in brackets under the title of the Association, as by so doing it would signify to anybody with whom the Society might correspond with that the Association was organised, and not an individual unit, thereby carrying more weight in any negotiations the Association might undertake.

It was proposed by Mr. Dudgeon, seconded by Mr. Snaith, and carried, that the words suggested by Mr. Noël Pillers be placed in brackets under the title of the Association on its printed matter.

Communication from Mr. W. C. Trevor, Clerk to the North Riding County Council enclosing scale of fees fixed by the Executive Committee as follows :—

At a Meeting of the Executive Committee held at the County Hall, Northallerton, on Monday, the 28th day of April, 1913. County Alderman Colonel A. F. Godman, C.B., in the Chair. It was resolved, that from the 1st May, 1913, until the further Order of this Committee, the following be the scale of remuneration of the Veterinary Inspectors employed by the North Riding :—

Five shillings for the first hour, and two shillings and sixpence for each subsequent hour in each day employed in his duty as Inspector.

For travelling, if by rail, third class fare, if by motor bicycle 3d. per mile for each mile travelled, and if by motor or by horse drawn vehicle, one shilling a mile one way from his residence.

For each microscopical examination, approved by the Chief Veterinary Inspector, 10/6.

For applying, when approved by the Chief Veterinary Inspector, the Tuberculin test to not exceeding two animals £1 ls., with 5/- for each additional animal, up to a maximum of £2 2s., with travelling allowance as above.

Actual cost of postages and telegrams to be refunded.

Letter from Mr. Pratt, Chief Veterinary Inspector to the North Riding County Council which stated that he had received the protest of the sub-committee of the South Durham and North Yorkshire Veterinary Medical Association at the Veterinary Inspectors not being allowed to make a microscopical examination of milk. He pointed out, however, that Veterinary Inspectors were not prohibited from making a microscopical examination, but that such examination must be approved by the Chief Veterinary Inspector before the fee for the examination is allowed.

Mr. MORTON thought that the North Riding Inspectors ought not to accept the scale of fees offered them, and was of the opinion that it would have been better if they had been allowed a free hand in carrying out the Tuberculosis Order, as was the case in Durham.

Mr. DUDGEON said that as there were a number of North Riding Inspectors present, now was the time to act if they had any protest to make.

The SECRETARY pointed out that according to the scale of fees, they as Inspectors were only allowed 3rd class railway fare, no fee was allowed for post-mortem examinations, no allowance was given for tuberculin or mallein, and it appeared that after six animals had been tested with tuberculin at the same time, and there were others to test, the remainder would have to be tested free of charge, as the maximum fee was £2 2s.

After a general discussion it was proposed by Mr. Dobbing, seconded by Mr. Morton and carried, "That the secretary write to the Clerk of the North Riding County Council asking him to bring the scale of fees to the notice of the Executive Committee with a request that an Inspector be allowed the same scale of fees as allowed by the Durham County Council."

CLINICAL CASES.

Mr. SANDERSON stated that one Saturday about noon he was requested to see some calves. He found one had died the previous night, one had been slaughtered just before he got to the farm, and one was very ill.

The one which was ill was chained in the byre, was breathing heavily and running forward with its head down. This one was removed at once into the fresh air and it gradually recovered. He gave a drench of sesquioxide of iron and mag. carb.

A post mortem was made of the one that had been slaughtered: on opening the rumen he was struck with the strong smell of prussic acid,

He then inquired into the age and feeding, etc., and found that the calves were four to six months old and were being fed on calf meal. The quantity used was 1½ lbs. of meal for 5 calves, and it was prepared by placing in cold water, which was boiled, and then allowed to cool. The calf that had died the previous night was the last one fed. The following morning two calves would not eat the meal, but of the two that did, one died, and the other was the one ill when he arrived.

He suggested to the owner the advisability of having the meal analysed, but as he did not appear willing he (Mr. Sanderson) had this done. He sent a sample to the Royal (Dick) Veterinary College, and Mr. Gemmell, Professor of Chemistry, reported as follows :—

"The meal contains a cyanogenetic glucoside. Prussic acid is liberated from the meal when mashed with water. The quantity of Prussic acid liberated varies according to the conditions. The following results were obtained :—

1. Mashed for one hour at 120° F. = 2.9 grains Hydrocyanic acid per lb.
2. Mashed overnight at room temperature = 2.4 grains Hydrocyanic acid per lb.
3. Mashed Saturday to Monday at room temperature = 3.8 grains Hydrocyanic acid per lb.
4. Mashed for one hour at room temperature, and two hours at 120° F. = 2.3 grains Hydrocyanic acid per lb.
5. Mashed overnight at room temperature, and 1½ hours at 120° F. = 3.6 grains Hydrocyanic acid per lb.
6. Mashed with boiling water, cooled to 120° F. and kept at 120° F. for 2 hours = less than 2 grains Hydrocyanic acid per lb.

Mr. SANDERSON further stated that in another case of what appeared to him to be prussic acid poisoning, since the above, there were three calves affected, one died, and the other two recovered when given fresh air. The blood of these animals appeared brick red and very frothy.

It had occurred to him that possibly many of the sudden deaths in young stock which one commonly heard of at farms and which were attributed to quarter-ill might be due to poisoning by prussic acid generated from linseed meal.

Mr. BLACKBURN said that he had been much interested with Mr. Sanderson's remarks, and about ten years ago he mentioned similar cases when reading a paper before the Association.

ELECTION OF OFFICERS.

President.—Mr. J. M. WALKER, F.R.C.V.S., West Hartlepool; proposed by Mr. Hill, seconded by Mr. Gibson.

Vice-Presidents.—Mr. W. AWDE, F.R.C.V.S., Stockton-on-Tees; Mr. W. N. DOBBING, M.R.C.V.S., Darlington; proposed by Mr. Snaith, seconded by Mr. Gibson.

Hon. Sec. and Treas.—Mr. J. H. TAYLOR, F.R.C.V.S., Darlington; proposed by Mr. Dudgeon, seconded by Mr. Hill.

Auditors.—Messrs. DOBBING and HILL; proposed by Mr. Snaith, seconded by Mr. Dudgeon.

Mr. DUDGEON proposed that the members and friends have an excursion again this year. He might say that he never enjoyed a day's outing more than he did theirs of last year, and suggested that Messrs. Dobbing, Hill, and Taylor be the committee and make all arrangements. This was seconded by Mr. Blackburn, and carried unanimously.

The SECRETARY stated that he had already been making a few inquiries and thought Wensleydale would be a nice place to visit this year.

PRACTICAL DEMONSTRATION OF THE MICROSCOPICAL EXAMINATION OF MILK.—By H. P. LEWIS, M.R.C.V.S. Assistant Veterinary Inspector for Sheffield.

Mr. LEWIS introduced his subject by remarking that in conducting such examinations, absolute cleanliness must be observed. All slides, coverglasses, pipettes, bottles, etc., ought to be sterilised, and he advocated indiarubber corks for the bottles containing the milk.

In drawing milk from the quarter of an indurated udder, his experience was that it did not very much matter which milk was used, whether the first or last withdrawn, as in such cases the bacilli would be found in any of the milk. The milk from an indurated udder was usually thinner than normal, and had a brownish tinge. He kept all slides and coverglasses in absolute alcohol.

Mr. LEWIS having brought a quantity of suspected milk with him allowed the same to stand, and from the sediment at the bottom of the bottle withdrew with a pipette a sufficient quantity which was centrifuged, after which the deposit in one of the tubes was smeared on a slide stained with carbol fuchsin and counter-stained with methylene blue in the usual way.

Every process during staining was carefully carried out and thoroughly explained, and on examination of the prepared slide the presence of the bacillus of tuberculosis was well demonstrated. Mr. LEWIS answered several questions which were put to him.

Mr. HILL proposed a very hearty vote of thanks to Mr. LEWIS for his kindness in coming such a long journey and giving them such a practical demonstration.

Mr. DUDGEON seconded the vote of thanks which was carried with acclamation.

Mr. LEWIS replied, saying that it had been a great pleasure for him to come, and if at any time he could be of any service to the members he would only be too pleased to help them in any way he could.

The members afterwards had tea together in the hotel.

JAMES H. TAYLOR, Hon. Sec.

Pituitrin in Obstetric Medicine.

Udacta (*Revista de Medicina y Cirugia Practicas*, October 14th and 28th, 1912) reported to the Spanish Gynaecological Society two cases of uterine hæmorrhage treated with pituitrin. The first was a woman two months pregnant, who had been passing coagula and large pieces of "flesh" which macroscopically appeared to be placenta. Three days after being first seen she had a slight hæmorrhage, and about six minutes after its appearance she was given a hypodermic injection of pituitrin. Fifteen minutes later she felt pain, and expelled from the uterus a quantity of blood. Forty two minutes later there came away a coagulum and a mass of placental tissue. That was the last of her symptoms, and she has remained well since. In the second case the patient's uterus expelled the placenta after the first injection of pituitrin. In the discussion, Botin said that he had experience of the action of pituitrin in 4 cases. In 3 of them the result was excellent; in the fourth case there was no result. He referred to the great difficulty in the experimental study of the action of the extract of the pituitary gland in the living animal. The operation for its removal was so severe that it was difficult to distinguish the effects of its removal from the effects due to the severe traumatism necessary in removing it. The recent introduction by Parache of the orbital method of reaching the gland involved much less injury to neighbouring parts, and may have better results. The injection of pituitrin causes first of all a tetanic contraction of the uterine muscle, which after a short time

ceases, and is succeeded by other contractions altogether resembling those of normal labour. Attempts to avoid the initial tetanic uterine contraction by giving smaller doses have not been successful. So far, pituitrin appears to be quite harmless to both mother and fetus. One peculiarity of its action is that tolerance seems to be very quickly established, so that even the second injection acts less energetically than the first, and the third than the second. For this reason, the drug should not be used in the first complication which occurs (unless this is really serious), as otherwise a later moment of greater danger will find us deprived of its full power of assistance. It results from its power of increasing the normal intermittent contractions of the uterus that it can often be used in uterine inertia before the child's birth, and in this way replace the use of the forceps. Manueco remarked that our knowledge of the drug was still much too incomplete to justify any enthusiasm about it. This might lead to its falling unduly into discredit. He believed that in the reactionary relaxation of the muscular fibres of the uterus following its use, hæmorrhage was to be feared. For this reason he always repeated the injection if the pains faltered towards the end of the labour. In every case an exact diagnosis of the cause of the delay in the course of parturition was essential. To use pituitrin, for example, in a case of pelvic contraction could only lead to a calamity. More study of the effect of the drug on the contractions of the uterus, by means of the locomotometer, was required.—B. M. J.

PARLIAMENTARY.

SHORTAGE OF CATTLE WAGONS.

In the House of Commons on Wednesday, June 18:

Mr. REDDY asked the Vice-President of the Department of Agriculture (Ireland) whether representations would be made to the Great Northern Railway (Ireland) Co. with regard to the shortage of wagons for conveyance of cattle from Banbridge, Co. Down, on days of fairs.

Mr. T. W. RUSSELL: The Department are unaware of any general shortage of wagons at Banbridge fairs. In connection with the fair on 27th ult., there appears to have been an excess demand as compared with the corresponding fair last year. The supply sent fell short in consequence by six wagons, but the requirements were met by unloading other wagons standing at the station containing goods. By these means traffic was got off in usual time. Representations to the Company appear scarcely to be called for in the circumstances.

Tuesday, June 24

DUTIES OF VETERINARY INSPECTOR.

Mr. Charles Bathurst asked the Secretary for Scotland if he would state what were the duties of the veterinary inspector to the Local Government Board for Scotland, and what were the veterinary qualifications required or the occupant of this post.

The Secretary for Scotland (Mr. M'Kinnon Wood): The duties of the veterinary inspector to the Local Government Board for Scotland are to supervise throughout Scotland the inspection of meat and also the inspection of cattle and dairies in relation to milk supply. The veterinary qualifications required have reference particularly to these duties.

Mr. Bathurst asked what diplomas or other educational distinction in comparative pathology or veterinary science and therapeutics Professor Leighton possessed, and what had been the nature and extent of his practice as a veterinary surgeon.

The Secretary for Scotland: Professor G. R. Leighton has been appointed veterinary inspector. He holds the following degrees and distinctions:—M.D., C.M., L.R.C.P. and S.E., L.F.P.S.G., and F.R.S.E. (Laughter) He has been connected with the Royal Dick Veterinary College since 1902, first as lecturer on comparative pathology and bacteriology, and latterly as Professor of pathology, bacteriology, and meat inspection. In that capacity, he has given lectures on diseases of animals, bacteriology of animal diseases, practical pathology, practical bacteriology, and meat inspection, and also demonstrations on healthy and diseased carcasses, the lectures on meat inspection and the demonstrations being conducted at the Edinburgh Corporation slaughterhouses. Professor Leighton has also a knowledge of Continental abattoirs, meat inspection, and methods of dealing with milk supply.

Mr. Bathurst asked whether any of the degrees which the veterinary inspector possessed was a veterinary degree, and though his duties were to be veterinary duties had he any veterinary education whatever.

The Secretary for Scotland said that he could not agree that Professor Leighton had not had a great deal of veterinary experience.

DOGS BILL.

The adjourned meeting of the Standing Committee A on the Dogs Bill was held on Wednesday, June 25th. Considerable debate arose, in which Sir Philip Magnus, Dr. Chapple, Sir Henry Craik, and others took part in opposing the Bill. The meeting of the Committee was adjourned until Wednesday, July 2nd.

DOCKING OF HORSES.

In reply to Mr. George Greenwood, Col. Seely said that representations had recently been made to the horse trade on this subject, and an order was now being issued to all concerned that after three years from this date no docked horse would be purchased for the Army.

FOOT-AND-MOUTH DISEASE (INDIA).

In response to Sir John Spear, Mr. Runciman said that the report of the Committee sent out to India by the Board of Agriculture to investigate the cause and treatment of foot-and-mouth disease in cattle had been completed, but the drafting of a detailed report had been postponed owing to the illness of Sir Stewart Stockman, who was not yet able to attend to business.

Tuesday, July 1st.

VIVISECTION EXPERIMENTS.

Mr. LYNCH (Clare, W. Nat.) asked the Secretary of State for the Home Department whether he could state the number of establishments in this country licensed for vivisection purposes or for research work involving experiments on living animals; how many persons were now in possession of licences and certificates authorising them to perform such experiments; how many dogs were employed for this purpose during 1912; what proportion that bore to the total number of animals so employed; and when the annual return of vivisection experiments would be published.

Mr. McKenna (Monmouth, N.)—The number of registered places in Great Britain is 109. The number of persons holding licences is 568. Most of the holders of licences also hold one or more certificates. The total number of experiments performed during 1912 was 83,599. I cannot give the exact number of experiments on dogs—888 experiments were performed under the certificates which allow experiments on dogs or cats, but the returns do not show how many were on either kind of animal. In addition to these, some of the 2,584 experiments performed under licence only, without certificate, may have been experiments on dogs. The annual return is almost ready for publication, and will, I hope, be issued shortly.

The Incidence of Tuberculosis in Cattle.

At the meeting of the Scottish Sanitary Inspectors' Association in Greenock, on Friday, 27th ult.:—

Mr. Peter McIntyre, M.R.C.V.S., Greenock, dealing with the "Veterinary Aspect of Milk Supply," said that the disease by far most prevalent amongst dairy cows was tuberculosis. With regard to the frequency of the disease in the different species of animals, a striking difference prevailed. During 1912, in the Greenock Public slaughterhouse, where a careful record was kept of every carcass found affected, no matter how slightly, the following were the percentages:—Bullocks, 11.5; bulls, 30; cows, 64.7; heifers, 13.4; calves, 16; swine, 11.5; sheep, .0008. It could be taken that the percentage of animals found affected with tuberculosis in any abattoir represented the actual percentage of animals affected in the country. The age and breed of the animal, and the conditions under which they were kept influenced greatly the percentage affected. Very great differences exist with regard to age; with each additional year of life the disease increased, so that out of the old milk cows which reach the abattoir an alarming number were found diseased. The percentage of Irish and Highland cows affected with tuberculosis was much less than the percentage found in heavy milking Ayrshires.

A striking example of the influence of environment on disease was demonstrated to him in the slaughterhouse. Authorities on pathology state that goats are practically immune to tuberculosis. Goats, being hardy animals, were seldom housed, and frequently were running wild on hill land. Such goats were usually free from tuberculosis, but of four goats brought for slaughter from steadings within the burgh, three were found to be extensively affected. These goats were living under practically the same conditions as, and along with cows. When one considered that the bovine tubercle bacilli had been shown to be more virulent for all animals than the tubercle bacilli of man, it must be accepted that milk, which was an important food, especially of children, if containing tubercle bacilli, must be dangerous to health.

The Tuberculosis Order, 1913, was the first legislative endeavour which would reduce appreciably the number of tuberculous cattle. An order somewhat similar was issued in 1909, under which local authorities had to pay the whole of the compensation due; it was strenuously opposed by them, and was withdrawn. In the new order, the Government contributed for the first five years one-half. This order was not a Public Health Act; it was administered, and the expenses paid by, the Executive Committees under the Diseases of Animals Act. In framing the order, however, the Board of Agriculture had been considering more the benefit to the public health than the welfare of the animals on whose behalf the Board of Agriculture was formed. No mention was made in the order of cows suffering from open tuberculosis of the lungs, a condition known to freely disseminate the germs, and to be a source of infection to animals in contact, and even to contaminate the milk indirectly. The order aimed at securing the destruction of every cow found to be suffering from tuberculous milk, as well as of all bovine animals which were suffering from tuberculosis with emaciation. (Applause).—*The Greenock Telegraph*.

GOVERNMENT PUBLICATIONS.—Messrs. Wyman and Sons (Limited), official sale agents in England and Wales for Parliamentary papers and Stationary Office publications, have published the following:—Protection of Animals: Overloading of Horses Bill, 1d.

Horse Shoe Competition.

The Roads Improvement Association has issued the details concerning its Horse Shoe Competition in which £100 is offered for a new or improved type of horse shoe that will provide horses with a satisfactory foothold upon the modern smooth waterproof road surfaces, and minimise the damage now caused to such surfaces by certain types of shoes now in use.

The Judges Committee comprises Mr. Robert Todd (Chairman of the R.I.A.) who is acting as Chairman; Mr. H. Percy Boulnois and Col. R. E. Crompton, C.B., representative road engineers; Mr. G. E. Fairholme who has been appointed to represent the Royal Society for the Prevention of Cruelty to Animals, of which body he is Chief Secretary; Messrs. W. Hunting, F. W. Stanley, and Thomas Wolsey are the veterinary surgeons on the Committee; Messrs. Henry J. Selby and Richard S. Tilling are watching over the horse-owner interests. The War Office have nominated Col. C. E. Nuthall as their representative. Messrs. J. H. Horton and Alan Lupton, well known in coaching circles, are also included in the Judges Committee.

Mr. Wallace E. Riche (General Secretary to the Roads Improvement Association) is acting as Secretary, and will be glad to supply copies of the rules upon request. Communications should be addressed to him at 15 Dartmouth Street, Westminster, London, S.W., and as no entrance fee is being charged all applications should be accompanied by 1d. stamp to cover postage.

RULES.

The merits of the competing devices will be judged mainly on the following considerations:—

(1) The provision of a satisfactory and non-slipping foothold for horses upon waterproof road surfaces now adopted upon main roads and the chief streets in our large cities and towns.

(2) The reduction in the amount of damage caused to road surfaces.

(3) General practicability, such as; capability of general manufacture, reasonable life, moderate cost and similar considerations.

Prizes.—It is proposed to award a prize of One Hundred Pounds for the device the Judges' Committee consider most satisfactory; but the Judges' Committee reserve the power to withhold the award if they consider that no shoe entered is deserving of a prize. Further, the Judges' Committee also reserve the power

to divide, or add to, the prize, if a number of horse shoes entered be equal in merits.

Entries.—Every entry must be made on an official form to be obtained from the Secretary to the Roads Improvement Association (Incorporated), 15, Dartmouth Street, Westminster, London, S.W. A separate entry form must be filled in for each shoe submitted.

Details.—The entry must be accompanied by a specimen shoe, or shoes, and a concise memorandum giving general features of the device and its claims. The memorandum and sample shoe, or shoes, submitted will be treated as confidential, and for the Judges' information only.

The Memorandum should give information under the following headings:—

(1) Full name and address of entrant.

(2) Cost of production of the shoe, or shoes submitted, and also estimated price at which reasonable quantities could be supplied.

(3) General statement of the claims for the shoe submitted.

(4) Whether the type of shoe entered has been used for any period and, if so, details.

(5) Whether shoe submitted is now on the market, if so, how long it has been available, names of representative users, and extent of sales.

Date of Entering.—The latest date for receiving entries is December 31st, 1913. No formal entries with the accompanying shoes and memoranda should be sent before December 1st, 1913.

Man Injured by Humane Killer.

A shooting accident took place on 17th inst. in the horse fair attached to St. James's Market, Bradford.

P.C. Carr was called, and found William Batty, of 107, Binbrook Street, bleeding profusely from a wound in the right thigh. A horse had been ordered by the R.S.P.C.A. Inspector to be destroyed, and Messrs. Bryant, horse slaughterers, of Thornton, came to destroy the animal by means of the humane killer. The instrument had been fixed to the horse's head and was discharged, and the bullet came out of the horse's neck and penetrated Batty's thigh. P.C. Carr rendered first aid, believing an artery to be severed, and the man was removed to the Royal Infirmary, when it was decided to perform an operation for the removal of the bullet.—*Bradford Daily Telegraph*.

Roads and Horses.

The International Road Congress, at present on a visit to Scotland, were entertained to dinner in the City Chambers by the Corporation of Glasgow on Monday.

Lord Provost D. M. Stevenson, in proposing the health of "Our Guests," said it was no use simply making roads for to-day or for the next two or three years; they must be made with an eye to the requirements of the future. Traffic should not be made to suit the road; the roads should be made to suit the traffic.

The Right Hon. Sir John H. A. MacDonald, President of the Scottish Automobile Club, submitted the "Lord Provost and Corporation of Glasgow." In doing so he declared that nothing would conduce more to the health of the community than the making of good roads and streets; and, let it be said with bated breath, the removal as much as possible of the poor old horse from the streets. Let them consider the question of the improvement of the road not merely from the point of view of easy, convenient, and economical transit, but of the health of the population, because every horse that went about the city was a promoter of disease. The most economical, the most practical, and the most sanitary mode of conducting transit through the streets was by mechanical means.

Lord Provost Stevenson, in replying, referred to Sir John's remarks, and said the transformation was going on very rapidly, and the time seemed not very far distant when the horse would appear in the street in a very ornamental position, say as the outrider of a circus procession. (Laughter).—*Daily Record and Mail*.

The Case for Vivisection.

The members of the Research Defence Society held their annual meeting at the Royal College of Physicians. Sir David Gill presided. There were also present Sir Thomas Barlow, Sir William Osler, Bishop Frodsham, Mr. Astor, M.P., and Mr. Stephen Page, hon. sec.

The Committee, in their report, appealed for a special fund of at least £600 for securing a ground-floor room, fronting on a good thoroughfare in London, where the facts of the case for vivisection might be put before the public. Towards this sum £240 had been received.

Lord Cromer referred to a paragraph in the report which stated that at the annual meeting of the Royal Society for the Prevention of Cruelty to Animals the re-election of Lord Cheylesmore to the council of that society was defeated on the ground that he was one of the vice-presidents of the Research Defence Society. He himself, and a good many others who were members of both Associations, instantly instituted a protest. He believed it was a snap vote, but if it should prove to be the matured opinion of the members, he would think it his duty to withdraw from the Royal Society for the Prevention of Cruelty to Animals.

Sir Hugh Bell said that in the same event he should take the same course as Lord Cromer.—*The Times*.

Anti-vivisectionist and Press-cuttings.

At the Annual meeting of the Research Defence Society the President, Sir David Gill, K.C.B., F.R.S., in the course of his address, said:—

"When press-cutting is employed to prove some narrow point, and is applied to the purposes of special pleading, it is capable of the gravest misuse. By the aid of press-cutting agencies the employees of the anti-vivisection societies are enabled to ransack the whole of literature—books and periodicals, medical and lay, old and new, for cuttings consisting of illustrations, paragraphs, sentences, or in some cases single words, which, isolated from the context that is needed to show their real meaning, can be used to support one or both of

these two ideas—namely, that experiments are useless, and that they involve cruelty. And the people who are engaged in the production of this concentrated extract of scissors and paste are the very last who are likely ever to realise how very misleading a product it is, both to producer and consumer.

Does not the habit of scandalmongering grow fast enough upon men and women who indulge in it, without it being made a means of livelihood.

REVIEW.

A MONOGRAPH ON JOHNE'S DISEASE (ENTERITIS CHRONICA PSEUDO-TUBERCULOSIS BOVIS). By F. W. TWORT, M.R.C.S.Eng., L.R.C.P.Lond., and G. L. Y. INGRAM, M.R.C.V.S. Illustrated with nine plates. Demy 8vo. Pp. vj. + 178. Price 6/- net. (Baillière, Tindall, and Cox, 8, Henrietta Street, Covent Garden, London).

Monographs upon single diseases are not abundant in the veterinary literature of this country. The subject of this one, with the names of its authors, will ensure it a wide reading, which it may be said at once that it fully deserves.

The work is designed "to summarise existing knowledge" of Johne's disease, and does so admirably. It includes an account of Continental investigations by different workers (particularly Bang and Miessner), the experimental work done in this country by the authors themselves and others, and the clinical observations of various practitioners. Clinical and pathological results are thus brought together into one small volume, which neither practitioner nor pathologist who is interested in the disease should neglect to read.

Practitioners will be most interested in the first five chapters, which deal with the history and distribution of the disease, its economic importance and etiology, symptomatology, differential diagnosis, prognosis, treatment, prophylaxis, and pathological anatomy and histology. The later chapters are concerned with the bacillus, its cultivation and special and general pathogenicity, diagnostic vaccines, and the agglutination and complement fixation tests. This latter portion is extremely interesting, though some of it is not of a nature to be of much practical utility to anyone outside a laboratory. It will thus be seen that the book treats of the disease from every standpoint, and all we need say of it is that the whole is well done. It will almost inevitably soon be out of date in some particulars, and probably the authors themselves will help to make it so. In the meantime, they have done the profession good service by its publication.

W. R. C.

Personal.

Mr. WILLIAM KEARNEY, M.R.C.V.S., a graduate of the Royal (Dick) Veterinary College, Edinburgh, has been appointed assistant veterinary pathologist to the East Africa Protectorate.

CHAPMAN—AUBREY.—On the 26th ult., at St. Mary's Church, Tyndall's Park, Clifton, by the Rev. F. Norton, Harold Chapman, of 15 Upper Wimpole Street, W., to Maud Evelyn, eldest daughter of Mr. and Mrs. Thos. Aubrey, of Clifton, Bristol.

ABBOTT—KITCHIN.—On Saturday, June 21st, at Woodford Green Congregational Church, by the Rev. Eynon Davis, Cecil Alfred, son of Mr. and Mrs. J. B. Abbott, of Montclair, Woodford Green, Essex, to Kathleen, second daughter of Mr. J. E. Kitchin, M.R.C.V.S., and Mrs. J. E. Kitchin, of Overdale, Woodford Green, Essex, and Shipborne, Cromer.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, July 1.

REGULAR FORCES. ARMY VETERINARY CORPS.

Capt. A. C. Anderson is seconded for service with the Egyptian Army. Dated May 2.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

Maj. A. E. Clarke, retired pay (late Army Veterinary Corps) is appointed Assistant Director of Veterinary Services of a Territorial Division, and is granted the temporary rank of Lieut.-Col. in the T.F. whilst holding the appointment. Dated June 25.

OBITUARY.

J. B. THOM, M.R.C.V.S.

Graduated, Glas.: May, 1904

News has just reached Liverpool that Mr. J. B. Thom, M.R.C.V.S., late Assistant Veterinary Superintendent to the Liverpool Corporation died in South Africa on 2nd April. The deceased gentleman was about 35 years of age, was a native of Glasgow and held his Liverpool appointment for several years.—(*Local Government Chronicle*, June 14).

HENRY THEAKSTON, M.R.C.V.S., Pocklington, Yorks.

Lond.: April, 1879.

Mr. Theakston died on June 18th from chronic nephritis. Aged 56 years.

FRANCIS TOMPKINS POWELL, V.S. (retired), Gamlingay, Caxton, Cambs., died on June 23rd from bronchitis. Aged 84 years.

SUSPENSION OF THE UDDER IN MAMMITIS.

Sir,

I have read Mr. Lockwood's paper on mammitis and the report of the discussion thereon with much benefit. I do not find any allusion to the practice of giving support to the painful and inflamed udder by means of a suspensory cloth. I believed that such a measure was extremely beneficial, and in consequence I always have the udder supported in this way.

As no reference was made to the procedure, am I to assume that my belief in the consequent improvement in these cases is but one of the many fatuous illusions so common and peculiar to recently qualified men?—Yours faithfully,

W. F. POULTON.

INSPECTORS' FEES.

Sir,

I consider Mr. James Yule Bogue deserved the admiration if not the thanks of the profession for having the backbone to claim fees commensurate with his position as a learned professional man in a responsible undertaking. I for one congratulate him in getting what he rightly believed to be the value of his services to the community. Every reasonable man will, no doubt, allow that it is only fair when one undertakes great responsibilities, one should be compensated accordingly.

On the contrary, I am very sorry to see that some of our number estimate their time and skill at 3/6 per hour and consider that sum is sufficient for any man, who undertakes responsibilities as they are disposed to undertake. To my mind the acceptance of such a sum seems to indicate that in some country districts the practitioner values his time and skill very cheaply or perhaps he has very little to do to occupy his time elsewhere.

Apparently it is useless for the National Association to be working its hardest to obtain a suitable remuneration for those veterinary surgeons working in the public service when there is another section of the profession working against the principles of that Association.

Every right-minded member of the profession must feel sorry at the action of Town Council in dismissing Mr.

Bogue from further attendance on the Council's horses because he asked for what he considered was reasonable, especially under the circumstances.

If veterinary surgeons are so narrow-minded as to work against those of their brethren who adopt a higher level than the majority seem to place themselves, then the majority must sink to a very low level, lower in the future than in former times. (Messrs. Crowhurst and Toope should make an incursion westward).

I agree with Mr. James Blakeway when he says the preachings of professional ethics at veterinary societies don't agree with the performances in practice. Probably some of the praters infer: "Don't do as I do, do as I say." There is too much cant, too great a number of petty selfishnesses to satisfy, too many little minds to reform, and too much sham mutual admiration in our profession. We should submit ourselves to introspection before we rave in veterinary societies about our own importance and competence and the greediness of the medical profession and other bodies. Are we sound internally? Personally, I think the public give us our worth. Seemingly many of us do not understand logic. Perhaps too many of us have never heard of *Vis unita fortior*. If all of us have, then where does our wisdom come in? Don't blame the public!—Yours, etc.

HENRY GRAY.

Sir,

It is a pity that the brief for the defence of the Council was not placed in the hands of an individual who had at least the ability to write in terms of ordinary politeness. "Diogenes the First" describes my letter as "asinine." Well, I hope that I am not exceeding the bounds of propriety if I describe his production as "porcine." He is distinctly greedy. His equanimity is seriously disturbed because I have written under the *nom de plume* of "Diogenes." He says that he used this title "years ago." I may inform him that I have also used it on several occasions and I dispute his exclusive right to the title.

But *ma foi*, if his former letters were couched in the style of his present one, I should certainly have adopted another title, as it would be very distressing to be mistaken for such an egotistical and greedy individual.

His letters (so he says) "were of some little good to the profession." "The Lord gie us a good opinion of ourselves."

Now Mr. "Diogenes the First," you assume far too much. You may be as "much incensed" as you please, but everyone is entitled to his own opinions and it is a free country. If you were the "Shah of all the Persians," you might get "letters patent" or "vested rights" in a *nom de plume*, and might try to demolish all those who differ in opinion with you. You *should* be a member of Council, that job would suit you. But as you are only an ordinary individual (at least we hope so), don't be too "cock sure" that "all serious disputes about that Bill inside the profession is dead." Better "wait and see."

With reference to the 19 members of Council you mention, I beg to point out to you that the majority of them are well-off city practitioners, who know nothing about the requirements of veterinary surgeons in the country. If you hold they do, then we shall "agree to differ." I suppose you will not deny that the scarcity of country practitioners on the Council is a matter that is often the subject of comment. Your second list does not contain the names of any men who can be regarded as conversant with the calving of cows, the foaling of mares, or the castration of colts. As for the third list, I hardly think that anyone can seriously suggest that the members mentioned are representative of the rank and file of the profession.

I again assert that the teachers "rule the roost," not by numbers certainly, but by influence. If "Diogenes the First," thinks otherwise, he is welcome to his opinion, it will not alter mine, although he may describe the view as "dangerous," a "pernicious superstition" and "rubbish." What convincing terms there are in a discussion, even when adopted by "a veterinary correspondent"!—Yours, etc.,

"DIOGENES" (THE ORIGINAL).

No. 1305.

JULY 12, 1913.

VOL. XXVI.

THE COUNCIL MEETING.

Last week's Council meeting, though the report of its proceedings is somewhat voluminous was not in reality a very long one. It commenced with a change of Presidency; and Prof. Mettam, after serving two years as President with much more than ordinary distinction, transferred his chain of office to Mr. Carter. The new President has earned his position by many years of good if quiet work upon the Council; and his election will be popular amongst practitioners.

After the election the Council passed to a variety of business, some of it very important. The most import of all is finance; and here we can only echo the words of the Treasurer "on the old lines." We have less than £60 in hand; shall require about £150 during the next three months, and only one resource is open to us. Though it is little more than a year since we sold £1000 worth of Consols, yet before the end of the present year we shall be forced to sell more. That is the situation; and it requires no comment.

Meanwhile the meeting yields ample evidence that, as our exchequer is dwindling, our financial needs are expanding. The Parliamentary Committee had even more work than usual upon Parliamentary Bills to report; and their labours have included the sending of a special deputation to Edinburgh. Happily all their work this quarter seems to have progressed satisfactorily; but its cost must be increasing.

The Library Committee, too, illustrated the poverty of the R.C.V.S. Proposals were made to increase its supply of periodicals, but these were negatived on the grounds of expense. On the same ground, the Council refused to sanction any circularisation of the books. We agree that both decisions were unavoidable—and so the books must remain inaccessible to nearly all members, and the Library must continue to be all but destitute of periodicals.

The Registration Committee had to deal with the recent appointment of a medical man to a veterinary inspectorship in Scotland, and the matter is being taken up vigorously. The Council

intend to "strongly protest" to the Local Government Board for Scotland, and, as a small but strong special sub-committee has been appointed to draw up the protest, it seems that some especial case is to be given to it. We shall all await the result with interest.

Finally, a great deal of attention was given to educational matters, and these we reserve for future notice in detail. Some of them are very important indeed, for readers will see that, in more directions than one, radical alterations are proposed. We advise all members, therefore, to study these new proposals carefully.

THE SANITARY INSTITUTE CONFERENCE.

The Veterinary Inspectors' Conference opened at 10 a.m. on Wednesday, in the University College, Exeter. There was a good attendance—the lecture theatre was filled; there were many veterinary inspectors, with several M.O.H. and sanitary inspectors. Prof. Penberthy filled the duties of chairman admirably, and gave a clear and reasoned introductory address. Naturally tuberculosis and milk were the predominating feature. The paper by Mr. W. Ascott on "Milk and Dairies" was to the point, well set out, and not too long. Mr. G. P. Male and Mr. J. A. Dixon spoke, in the main supporting Mr. Ascott. Dr. Freemantle, M.O.H., in a temperate contribution to the discussion, acknowledged the propriety and the value of veterinary co-operation in the work, and with Dr. Garnett, M.O.H., expressed the view that veterinary surgeons would be met and welcomed by the medical officers. Mr. Stableforth's paper, "Bovine Tuberculosis, its Diagnosis," was not efficiently discussed—it was talked round—in spite of the efforts of the Chairman. The discussion on Mr. Archer's paper, "Transmission of diseases by animals to man," was also discussed, and brought to light once more the old story of the infection of scarlet fever from cows. The final paper on abattoirs and freibanks, though less directly veterinary in character, was freely discussed; and the Conference closed at 2:30. We hope to publish details later.

THE TREATMENT OF PLEURITIC EFFUSIONS.

With reference to Major Martin's article in your issue of January 25th, I beg to give particulars of an interesting case, which was recently treated in the Station Veterinary Hospital, Bulford, on the lines indicated.

Subject. Well-bred pony mare, 5 years, about 14 hands.

June 5. First called in. Patient dull and off feed. Has fever, and coughs a little. Had been kept in hot stuffy stable.

June 6. Still dull and not feeding, but grazes fairly well when turned out in paddock.

June 7. No change. Patient still dull, and won't touch corn, mashes, or hay.

June 8. Brought to Hospital, will eat nothing. Very dull. In evening, respiration slightly accelerated. Pulse hard, wiry and frequent.

June 9. Blowing hard. Completely off feed. Looks distressed. Pulse much accelerated. In morning removed half a bucketful straw-coloured exudate from chest, off side.

June 10. Blowing less. Picks a bit of green stuff. Membranes injected. Pulse better but weak. In morning tapped chest again on off side, and removed similar quantity of fluid with same characters. Tried again in evening, off side, but trochar entered too low and only a little blood flowed.

June 11. Much improved. Takes mashes and corn. Respiration almost normal. Pulse strong and steady. Removed three-quarter bucket effusion in morning and one and a quarter buckets in evening. Near side each time. Colour light port wine.

June 12. Normal pulse and respiration. Patient much pulled down and weak on her legs, but looks bright and feeds well. Inserted trochar and canula twice in morning on near side. First time no result as direction was wrong, the instrument being inclined too far back. At next attempt half a bucketful was removed, the same colour as yesterday. It was still running hard when canula was withdrawn. In evening, operation was repeated on off side. One bucketful obtained. Same appearance.

June 13. Continues to improve rapidly. Moves about easily in box, and is getting greedy. Performed paracentesis again in morning, off side, getting a bucketful of fluid, which was coming freely at finish.

June 14. Out of immediate danger. Lies down a good deal during daytime. Coughs occasionally. Tapped chest for last time in evening, near side, and obtained nearly half a bucketful, colour being now lighter.

June 15. Improvement maintained in every respect.

June 16. Doing well. Led out to graze and exercise.

June 17. Turned out to graze in paddock and commenced to gallop about.

It will be seen that this animal's chest was tapped ten times in six days, the total quantity of

fluid removed being seventeen gallons, two pints. She was in no way upset by the operation.

Improvement was noticeable after the first puncture, and was maintained proportionately to the amount of fluid removed. Tapping was discontinued as pulse and respiration had been normal for some days, and there did not appear to be any further need for it. Probably a considerable quantity of effusion remained in the Pleural cavities, to be reabsorbed in the course of time. Up to the present date (July 4th) there has been no synovitis of the Flexor tendon sheaths, nor lameness, as was observed in certain of Major Martin's cases, but it would be premature to say that such may not take place.

P. V. BEATTY, Capt. A.V.C.

Bulford, July 4th.

ABSTRACTS FROM FOREIGN JOURNALS.

SUBCUTANEOUS EMPHYSEMA IN A COW.

Humann, of Ebern, reports the following extraordinary case. In the first place, while on a journey, he was suddenly called upon to treat a case of milk fever; and, not having an air infusion apparatus with him, he improvised one by fitting a teat-canula on to the tube of a bicycle pump. This was completely successful so far as the milk fever was concerned, as the cow was up again and feeding after two hours. It was, however, followed two days later by a rather severe and protracted mastitis, attributable to infection by unpurified air. The treatment by means of the bicycle pump was witnessed by five or six men, who were much impressed by the simplicity of the method and the rapidity of its results.

About three months later, Humann was called to another cow in the same neighbourhood. The account given was that the cow had calved four days before, and now refused food; was distended over the whole body, which emitted loud rustling sounds when the hand was lightly passed over it. From this, Humann expected to find injury to the genital passages during parturition, and sepsis with malignant oedema. On arriving at the place, he found this opinion wrong; for the cow showed no fever, and the genital organs were completely normal. On the other hand the animal's whole body, from the neck to the tail and from the back to the udder, appeared inflated. Palpation of the body yielded loud rustling and crackling sounds, without the cow showing the least pain when the skin was strongly pressed upon or pinched together. No questioning could elicit any possible explanation of the condition, the only account that Humann was able to obtain that day being that the symptoms had arisen suddenly and quite spontaneously, and that no one could suggest any cause.

Humann treated the case symptomatically. First he made numerous punctures of the skin along the back, which allowed the air to stream out with a hissing sound. He then ordered frequent rubbing and massage of the whole body, and

further directed warm bran drinks to be given. The cow was apparently feeling quite healthy.

The next day the animal's condition, although not normal, showed a marked improvement. Further questioning now brought out the true history of the case, which was as follows. After calving, the cow had not risen, and all efforts to get her up had proved unavailing. Neighbours had then advised the owner to treat the case as Humann had been seen to treat the one of milk fever in the same neighbourhood three months before, and pump air into the udder. A bicycle pump was therefore again used, and the quill of a goose-feather was arranged as a canula. This apparatus had been employed upon the udder, the cow had forthwith risen, and immediately afterwards the distended condition had been noticeable, and the cow had become ill. Humann infers that in some manner, while the air was being pumped into the udder, a great quantity of it had found its way into the subcutis. The sequel of the case was that the cow recovered completely.—(*Münchener Tier. Woch.*)

CASES SIMULATING MILK FEVER.

Dun, of Hösbach, records the two following cases. The first was a cow at her fifth parturition, which showed a torsion of the uterus to the right, of 45°. She was raised behind with pulleys and well supported with straw, and it was then easy to reduce the torsion by turning of the calf, and effect delivery. The cow was let down, but a short time afterwards, before Dun had left the farm, he was again summoned to her. He found her lying upon the right side, with the head resting against the left ribs. The surfaces of the body were peculiarly cool, and showed no reaction to stimuli and pin-pricks. The eyes were closed, and the pulse was "galloping" and scarcely perceptible.

Dun gave her two hypodermic injections of caffeine within 15 minutes, and infiltrated the udder with air in the interval between the injections. This caused a sensible improvement in the comatose condition; the cow was soon able to raise her head, and also made attempts to rise. After the lapse of an hour, however, the threatening heart weakness again became evident, and it was then decided to slaughter her.

Post-mortem, a quantity of blood was found in the peritoneal cavity. This had proceeded from a small abrasion of the uterus, which had caused opening of the uterine artery. Dun concludes that during the intra-uterine turning of the calf the uterus had undergone a brushing and abrasion against the sacrum, which had led to fatal internal bleeding.

The second case was a well-nourished cow at her second calving. The history was that the day before, with the aid of several men, she had been delivered of a robust bull-calf. The cow was very heavy, and lay persistently before parturition, which finally took place while she was lying in a sloping position, with the fore part of the body higher than the hind.

The day after calving the cow had not yet risen,

but was feeding and ruminating, so that the owner did not seek advice until symptoms similar to those of milk fever had appeared. Dun found the cow lying athwart the stall in an apathetic condition. The head was laid sideways, the skin was icy cold, and the corneal reflex was absent. Dun immediately injected caffeine, and then proceeded to a liberal air infiltration of the udder. While the udder was being massaged the cow rose and took some brand drink. In the course of the night, however, threatening symptoms again appeared, and the owner slaughtered her.

Post-mortem, about four feet of the jejunum was found coloured blue-black, pressed together, and showing slight lacerations of its serous covering. Dun infers that in consequence of the position of the cow during parturition this portion of the intestine had been crushed in the pelvis. It is noteworthy that the severe injury to the intestine had not suspended peristalsis, for after the cow had risen, very copious defecation took place. The injury had, however, been followed by great depression, the symptoms of which resembled milk fever.

Dun attributes the transient improvement which followed his treatment in both cases to the vaso-motor effect of the caffeine, by which the brain obtained an increased current of blood. He regards the infusion of the udder as having been quite useless. When the artificially raised blood pressure subsided again, further depression followed. Moreover, in the first case, Dun considers that the caffeine really accelerated the fatal course of the illness by increasing the internal hæmorrhage.—*Münchener Tierärztl. Wochenschr.*

CARDIAC INTERMITTENCY IN THE HORSE.

Dreyer reports (*Zeitschr. f. Veterinärk*) the results of investigations he has made to determine the frequency of cardiac arrhythmia in the horse. He examined all the horses of two regimental squadrons with this end in view, and the results were surprising. Out of 272 horses he found 42 (equalling 15.5 per cent.) affected with intermittence of the pulse and heart. The cases were fairly evenly distributed between the two squadrons.

Five horses showed regular intermittences (at the fourth, fifth, or sixth heart-beat). In all the others the intermittences were irregular. The irregularities did not always exist in equal intensity in the same case, but showed variations. In most of the horses the irregularities increased in consequence of movement. The sounds of the heart were always pure, and the heart-beats were generally of normal strength. The proportion of affected animals rose with age—for instance, 36 per cent. of horses from fifteen to eighteen years old were affected, and not quite 6 per cent. of horses from four to six years old.

As causes of the condition, Dreyer suspects nervous disturbances, the strain of work, equine pneumonia, and influenza.

Some of the affected horses were poor workers, but in most cases there was no diminution in the

capacity for work. Only longer observation can yield a conclusion as to the significance of the affection.—(*Berliner Tier. Woch.*) W. R. C.

ASPERGILLUS FUMIGATUS POISONS.

Two toxins are produced by this fungus, one a convulsivant soluble in ether, the other a depressant insoluble in ether and volatile.—*Ann. Inst. Pasteur.*

[This fungus has not yet been cleared of complicity in the enzootic paralysis of horses noted in S. Australia, the depressant seems the more common toxin there. Trans.]

BOVINE ONCHOCERCHIASIS.

It appears most likely that *Stomoxys calcitrans* is the insect host concerned in the transmission of the embryo of this parasite from host to host. Embryos from the worm nest are occasionally liberated into the blood stream, and this fly has the opportunity to imbibe one or more of the sparsely distributed embryos, and after a partial development to inoculate a fresh vertebrate host.—*Jour. Trop. Med. and Hyg.* F. E. P.

YORKSHIRE VETERINARY MEDICAL SOCIETY.

The Spring meeting was held at the Hotel Metropole, Leeds, on Friday, April 25th, at 4 p.m. The President, Mr. J. Abson, Sheffield, being unavoidably absent, the senior Vice-President, Mr. A. McCarmick, Leeds, was voted to the chair, being supported by the following members: Messrs. S. Wharam, H. G. Bowes, F. Somers, G. E. Bowman, A. W. Mason, G. C. Barber, W. Crawford, Leeds; E. H. Pratt, Northallerton; A. Ellison and W. Edmondson, Harrogate; J. McKinna, Huddersfield; A. W. Noël Pillers, Liverpool; T. C. Fletcher, S. E. Sampson, and H. Thompson, Sheffield; S. Chambers, Kirkheaton; G. W. Carter and H. M. Holland, Keighley; G. W. Davidson, Wetherby; F. W. S. Clough, Halifax; J. R. Simpson, Ripon; J. A. Hodgman and M. Robinson, Barnsley; G. Whitehead, Batley; W. P. Weston, York; C. Pitts, Bradford; P. Deighton, Selby; J. M. Bell, Brighouse; H. Pollard, Wakefield; J. S. S. Woodrow, Swinefleet; and J. Clarkson, Hon. Sec. Mr. A. A. Walker, Harrogate, was present as visitor. The minutes of the previous meeting, as published in *The Record*, were adopted on the proposition of Mr. Bowes, seconded by Mr. Robinson.

Apologies for non-attendance had been received from The President (Mr. Abson) and Messrs. Cockburn, Pratt (Ripon), Lloyd and Lazenby.

A letter from Mr. Lloyd, Hon. Sec. North Midland Society, was read suggesting that a joint summer meeting be held at Sheffield. This was considered to be an excellent suggestion, and on the proposition of Mr. Chambers, seconded by Mr. Wharam, the Council was instructed to make the necessary arrangements.

New Member. Mr. P. ABSON, Doncaster, was unanimously elected a member of the Society on the proposition of Mr. J. McKinna, seconded by Mr. H. G. Bowes.

Mr. TAINSH, Grimsby, was nominated by Mr. J. S. S. Woodrow.

The Report of the Council on the "Milk and Dairies Bill" was read by the Secretary and Mr. Pillers and Mr. Fletcher spoke in reference to it.

National Veterinary Association "Inspectors' Fees." Mr. PILLERS suggested that the scheme of the National Association should be taken as a basis in order to obtain better terms for the Inspectors in various districts.

After some discussion Mr. E. H. Pratt proposed that the best thanks of the Society be given to them for bringing the matter forward and that the Society do its utmost to adhere to the scheme as laid down, seconded by Mr. Pollard and carried.

THE TREATMENT OF PSOROPTIC MANGE IN THE HORSE.

By A. W. NOËL PILLERS, F.R.C.V.S.

Mr. Chairman and Gentlemen,—When your President asked me, on March 28th, to give you a paper on some parasitic affection, at the end of April, I hardly knew what to choose. I need not say that at all costs I was determined to do something to try and show the Society and Mr. Abson how greatly I appreciate the many kindnesses which both have extended to me on so many occasions. During the various discussions on parasitic diseases which seem somehow or another to arise when I join in a group of practitioners, I am often reminded that life histories and bionomics are all very well in their way, but that treatment is the one important thing. Schmidt and his cure for milk fever is the glorious example which is often quoted. I therefore wish to make a few remarks about the treatment of psoroptic mange in the horse.

I do not want any other point or animal brought into the discussion, and then I am sure that we shall all learn a great deal from the experiences of so many old practitioners. I do not intend to bother you with such important details as to how the animal became infected, or how the infected horse passes it on to his stable companion, or that the parasite can be seen easily on the skin in the immense majority of cases, or what happens to the *Psoroptes communis equi* when various bland oils or fluids are poured on it, under the microscope.

Our horse has psoroptic mange, uncomplicated, which is by far the commoner of the two scheduled forms, and we want to cure him absolutely without any references to his harness or surroundings.

The remarks which are about to be made are based on the records of 824 cases treated in different ways, and although you will most likely disagree strongly with what I am going to say, I feel sure that if you kept a similar record you would be forced to the same conclusion. Now the psoropt lives on the skin, and is not difficult to kill, so that if one observes the following principles in detail, treatment should be successful in a minimum amount of time. It is the time that animals are kept in the stable that is one of the team-owners' greatest grievances against the Parasitic Mange Order of 1911. The success of treatment depends upon the strictest attention to details which may be better termed minutiae.

1. **Clipping.** It is essential to clip the animal down to just below the stifles and elbows; there are many cases in which this is not done, either the owner has some peculiar ideas as to the value of the winter coat, or he is afraid of spoiling the animal's spring coat. I know veterinary surgeons who do not consider clipping necessary, but if they were to analyse the results of their cases with regard to toxic symptoms, secondary pneumonia, and recurrence, they would be surprised. This mange is a disease of winter and long coats, and the value of removing the "cover" for the acarus is all important. I consider that the mane and tail should also be removed, because the parasite is in these places capable of obtaining a living without producing lesions of clinical importance for several weeks or even months.

Besides reducing the death rate from toxic symptoms and pneumonia, a clipped animal uses less dressing. It is often wise in badly affected cases to use an old pair of clipping blades on account of the liability of scurf to

break the teeth. Clipping has other values; it reduces the activity of the parasite in winter, and so has a therapeutic value; it also shows the full extent of the disease. I cannot speak authoritatively with regard to the value of slow yet careful gas singeing immediately after clipping. In a few cases I found it apparently hastened a cure, whilst in others nothing appreciative could be noticed. If the weather and animal be warm, then it kills a great number of the causal parasite. If the treatment described hereafter be carefully carried out, I do not think singeing is necessary.

2. Removal of abnormal epidermal products. This is the next most important step. It is simple or difficult according as to whether the case is a recent and untreated one, or an old standing and blistered skin. It is to be accomplished by the addition of about 2 to 3 ozs. of soda, or acetic acid, to the gallon of hot water and using this on the animal's body with soap. A most important point here is the choice of a suitable soap. Many soaps blister the horse's skin, and this is the one thing that must not happen if a cure is to be effected. Roughly speaking, any soap that can be used on a man's face and arms will be safe. After the animal has been lathered and soaked all over, the scrubbing brush will remove practically all the scales. Special attention will have to be paid to the mane and tail, and also to seeing that the animal is washed absolutely all over. There is no great objection to the addition of a little of one of the coal tar disinfectants to the water at this stage, although I think that it can just as well be saved for other purposes. After all the soap has been removed by warm water, the animal should be dried, rugged and exercised, and bedded on straw. With proper grooming and exercise, many recently infected and untreated cases will recover without further treatment. I do not recommend stopping here, however, but only mention it as bearing out the chief aim of this paper, viz., to show that in my experience, treatment is more often than not, too energetic, and worse than the disease.

3. Application of an anti-psoric dressing. On the day after washing, the animal has to be dressed with some agent which will kill the parasites that have survived their drenching in soap solution. The choice of an improper agent for this is by far the commonest cause of error in the treatment of this mange. I cannot do better than quote here in full a few remarks from Megnin:—

"On s'attaque à la cause déterminante, c'est à dire au sarcopte, par des agents qui ont la propriété de tuer le parasite. Mais si les parasitocides sont nombreux, il y a un grand choix à faire parmi eux; beaucoup sont dangereux, et il ne faut pas s'exposer, en voulant tuer une mouche, à écraser la tête de celui qui la porte, comme l'ours de la fable, certainement on guérira la gale sarcoptique avec le pétrole et la benzine, mais en causant, en même temps, une irritation de la peau, qui persistera pendant de longues semaines, en provoquant l'apparition d'une affection artificielle qui a autant d'inconvénients, au point de vue de l'utilisation de l'animal, que la gale elle-même. C'est ce qui résulte d'expériences nombreuses et répétées que nous avons faites. Ces mêmes expériences nous ont démontré qu'on peut guérir la gale au moyen de substances qui tuent l'acarus en laissant à la peau tout la souplesse et toute la netteté, ce qui permet l'utilisation du cheval immédiatement après sa guérison, qui peut être obtenue en huit jours.

Il y a deux substances qui sont deux acaricides par excellence—le soufre et la nicotine. Ces substances mêlées à des excipients doux comme les corps gras liquides ou non, constituent les meilleures préparations contre la gale. On peut préparer une pommade soufrée, économique avec des graisses communes allongées d'huile, qui est très efficace, dans la proportion de 200 grammes de soufre sublimé pour 1 kilogramme de graisse.

Le carbonate de potasse qui entre dans la pommade d'Helmeric, du *Coder* est parfaitement inutile."

You will notice his strong remarks concerning drug dermatitis, that the disease can be cured in eight days, the high position occupied by sulphur and nicotine as parasitocides harmless to the skin, and the uselessness of alkalies in the dressing. My experience with this form coincides exactly with Megnin's of sarcoptic mange, with one exception, viz., that tobacco dust, which is used on account of its nicotine containing properties, varies greatly in its composition, and I have seen several deaths from its employment. Oil and sulphur are then to compose our dressing. The sulphur demands no comment, but the choice of a suitable oil is most difficult, both from the therapeutic and pecuniary aspects. A suitable oil must not blister the skin, nor dry with a varnish-like layer, nor tend to turn rancid, nor prevent the normal functions of the skin taking place. In addition to these, it must be cheap. It is most difficult to get an oil to answer all these requirements and one has to fall back upon the least harmful.

There are many bodies such as lard, lanoline, vaseline, or petrolatum (suet, horse fat and goose grease are rarely used in veterinary pharmacy) and palm oil, which although occasionally employed can be discarded at once. They are dangerous when applied over large surfaces. Rape, linseed and castor oils either cause dermatitis soon after application, or later on by forming a varnish-like film; olive oil is too dear, in addition to its tendency to become pasty in cold weather, to oxidise in air, and then go slowly rancid. The least dangerous oil is, I think, train oil. It is cheap (April, 1913, 2.9 gall.). I have recently heard cotton oil spoken highly of. A peculiar feature about most oils is that for a period you will have no untoward damage to the skin, and then with the advent of a new supply of oil, comes marked skin corrugation in the treatment of your mange cases. This may be due to substances used in the refining process having settled to the bottom of the barrel. The proportion of sulphur to oil will vary from 1:10 to 1:5 by weight. It is important that this dressing be supplied in an open vessel, such as a bucket, which can be stirred with a stick. Narrow necked opaque jars often contain several inches of sedimented dressing when broken. The animal should be covered twice, the near side and then the off, at an interval of 24 hours. Here detail is essential, places commonly missed are the forehead, mane, tail, submaxillary space, breast, and inguinal region.

4. Exercise and Friction to Skin. The animal must now receive night and morning a good grooming with a duster, which can be wrung out in a suitable solution of some coal tar preparation.

Exercise must be given twice a day. These last two items are as important as the others.

If a repetition of this course of the treatment is necessary, it can be undertaken on the 6th to 8th day, after which the animal should be able to resume work. The coat of a clipped and treated animal grows very quickly, and some time after returning to work, no harm can be done by again clipping and applying a dressing when it is at rest at the week end.

I know that mange cases are left in the stable and neglected, and that accounts for a great deal of the untoward sequelæ which we have to put up with. Many practitioners will recommend the addition to oil and sulphur of discentives, such as the alkaline carbonates or acetic acid; their work should, however, have been done before the dressing is applied. Oil of tar will be used by others. Some I know will laud tobacco refuse, but its varying composition is enough to my mind to bar its use. Lime and sulphur will have its advocates. Proprietary dips I have seen used extensively with terrible results. Admirable though many of them may

be, they lend themselves to careless or over anxious uses by horse-keepers or owners. If a small quantity is given out, half to be used in a bucket of warm water once a week, you may rest assured that the careful or careless man is most likely to use all the material in about three-quarters of a bucket of water and apply it for two or three days in succession with disastrous results to the skin. I do not think that watery dressings on the horse have given such good results as one expected. The damaged skin, now more prone to irritation, wants some bland oil to replace the deficient natural oil and protect the abraded surfaces from the action of the air or acrid discharges. What I want to insist is that our treatment must be mild. Perhaps it may be said that I am going too far in the mild direction. I am satisfied that I am not, but I am sure good will be done if some of the heroic treatments of to day are replaced by milder measures.

5. Terminations. Before starting to treat cases of psoroptic mange, it is well to take into consideration the animal's age, its value and the reliability of those who will have to attend it. If the animal is 14 to 16 years old, and worth about £10 to £15, and its attendants are going to forget all about the animal after its first dressing, then the most humane and economic treatment is a bullet; for death will result sooner or later under this neglect.

Acute dermatitis is probably one of the commonest results of many systems of treatment, the skin becomes so tender that further dressings cannot be applied, and the case passes into:

Sub-acute drug dermatitis with partial recovery. If any abnormal condition of the skin is set up before the animal has been dressed all over, or if all the scab is not washed off, then a complete cure is almost impossible, because the parasites migrate into the epidermal cover resulting from dermatitis, and the skin is so tender that they cannot be removed. I have found live parasites after two months of severe veterinary treatment: it is explained on these grounds. The time in the stable under this heading varies from 4 to 6 weeks, and it is only when the animal has oil applied to its coat and is left alone that it begins to improve.

Chronic drug dermatitis is a very common sequel, resulting from repeated applications of a dressing whose effects are only moderately drastic. The skin after about six weeks becomes very thick, and nothing but a run at grass and "time" will make much improvement.

Apparent recovery is the next in order. I say "apparent" because if the mane and tail have not been treated there is likely to be a recrudescence of the disease when the next cold weather sets in.

Death is a common termination of mange, it results from a blocking of the skin with oily dressings when the animal is covered all over at once and the oil dries, or is not kept moving by the duster, or by exercise. The train of symptoms here is that of fever. If the animal is covered with oil in the proper manner and left standing for a week, the lungs take on the extra work of getting rid of the watery vapour and so the natural defences are weakened. There is fever and death from gangrenous pneumonia. A great number of deaths occur about two days after the animal has returned to work. This is due to lack of exercise when under treatment, coupled with weakened lungs resulting from a semi-functional skin. I did not see one death from washing in water in winter in an outbreak of 24 animals. Death from chronic poisoning has, in my experience, been most commonly caused by tobacco dressings. Of the satisfactory termination, complete recovery, it is unnecessary to say anything.

DISCUSSION.

Mr. FLETCHER complimented Mr. Pillers on the excellent paper he had just read, and remarked that to

cure mange, according to the writer, was the very simplest matter possible, but in actual practice one does not always find it so, and many cases arise that would puzzle the simple remedy people. He thought it was often necessary to add something more drastic than sulphur and train oil, such, for instance, as some tar preparation or even paraffin, as it seemed in some cases necessary to almost blister the skin to effect a cure. He knew there was often some dermatitis after mange, which no doubt Mr. Pillers would say was due to bad treatment, but he must repeat that he did not always find the mild methods advocated, to be successful. He would also like to ask what form and what quantity of nicotine Mr. Pillers would use.

Mr. WHARAM agreed that cleanliness was the finest thing in the world, and was perhaps the most important factor in the cure of all parasitic skin diseases, and particularly mange. He related a story of a case of mange in a horse belonging to a skin specialist which he had attended and cured by very simple means.

Mr. POLLARD said that ten years ago he had a considerable amount of mange, and his treatment, though not drastic, was not quite so mild as advocated. He invariably had the animals clipped and dressed with a mixture of rape oil and sulphur, to which was added a little creosote, potass. carbonate, and paraffin. This treatment was used with great success, and usually only meant keeping the horses in for ten days, they being then generally fit for work.

Mr. BOWMAN after thanking the essayist for his very interesting paper, said he had had considerable experience of mange, and generally found little difficulty in its treatment. He generally used train oil and sulphur, with spirit of tar. Occasionally when the withers were badly affected he used, quite locally, a small quantity of mercurial ointment, 1 to 8.

Mr. G. W. CARTER said he had listened to Mr. Pillers with great interest, and thought the Society was greatly indebted to him. For the last few years he had only little to do with mange and he attributed this to the improved hygienic conditions. Years ago he saw very much more and had not had much difficulty in effecting cures. His treatment was that used by his father, and consisted of oil, sulphur, turpentine, and spirits of tar, and he had found the same treatment successful in dogs.

Mr. SAMPSON also thanked Mr. Pillers for his interesting paper, and said that during the last two years he had seen a good deal of mange. He considered that the treatment advocated by Mr. Pillers was too mild, and thought if all cases were so treated some of them would take much longer to cure. He preferred to err on what he regarded as the safe side, and use a stronger dressing such as the ones which had been suggested by several of the previous speakers.

He did not favour the use of rugs when the horse was clipped, as they absorb so much of the dressing and get so dirty. The stable should of course be warm, and no untoward result would occur. He agreed with one of Mr. Pillers remarks early on "The treatment's the thing."

REPLY.

Mr. PILLERS said he did not regard the treatment of mange as simple in all, but it is so in many cases. Five hundred and thirty-three cases had been reported in Liverpool, and of these 143 had died under treatment or were slaughtered, so he thought there was room for improvement. In many cases which recur it is possible the dressing has been faulty—say the mane or tail left. He wished to impress on his audience the great necessity of clipping and thoroughly washing. It is possible for the psoropt to live for twelve months without causing clinical symptoms. He still failed to see why blistering should be necessary to destroy a

parasite which lives on the skin and on its products. Tobacco as a dressing he did not like, it was too variable to be safe.

Mr. Wharam's remarks do not call for comment except to say that mercurial ointment is a very dangerous dressing.

He regarded Mr. Pollard's dressing as rather strong, but was pleased to hear that he got most of his cases to work in 10 days.

Mr. Bowman's treatment he considered quite good, but he did not agree with him—or it was not his experience that mange was such a simple matter as Mr. Bowman had found it.

In regard to Mr. Sampson's remarks, he preferred to use the alkali before dressing instead of including it in the dressing, as by that means the *débris* is removed before the dressing is applied, which is thus rendered much more effective.

In conclusion he thanked the members for the very kind way in which they had received and discussed his paper.

A vote of thanks to Mr. Pillers was very heartily accorded, on the proposition of Mr. McKinna, seconded by Mr. Bowes.

The SECRETARY then announced that a very pleasing duty fell to his lot. It would be within the recollection of those present that Mr. Pillers had given to each member the opportunity to attend a series of demonstrations which were extremely instructive and which had been very greatly appreciated by very many members of the Society, who did not wish the occasion to pass without marking their appreciation in a more practical way than by a mere vote of thanks, and in handing Mr. Pillers a fitted travelling bag, he said he hoped the two would have many happy journeys together.

Mr. PILLERS in reply, expressed his thanks for the handsome present, which he had not expected, as anything he could do for that Society he was very willing and pleased to do.

Afterwards those present were entertained to tea by the Society.

Royal College of Veterinary Surgeons.

FIRST MEETING OF COUNCIL.

A meeting of the Council was held at the College, 10 Red Lion Square, London, W.C., on Friday afternoon, July 11th. Prof. A. E. Mettam, President, occupying the chair. The following members were present:—Major-General Pringle, Major-General Thomson; Professors Bradley, Sir John M'Fadyean, McCall, Share-Jones; Messrs. Abson, Banham, Burt, Carter, Clarkson, Dunstan, Garnett, Hobday, Lawson, Mason, McL. McCall, McKinna, Mulvey, Packman, Shipley, Slocock, Sumner, Trigger, and Wharam; Mr. George Thatcher (Solicitor), Mr. Fred Bullock (Secretary).

MINUTES.

The minutes of the meeting of Council held on July 5, 1912, which had been printed and circulated, were, on the motion of Mr. Abson, seconded by Mr. Mulvey, taken as read and confirmed.

ELECTION OF PRESIDENT.

Mr. MULVEY: Mr. President, I have very great pleasure in proposing the election of Mr. Carter as our President for the ensuing year. Mr. Carter has been a member of this Council for some sixteen or seventeen years; he has been assiduous in his attendance at the

meetings of Council, and has done good work for the profession. It affords me very great pleasure to propose him as President. (Cheers).

Mr. LAWSON: I would like to second that motion, and in doing so to endorse all the remarks that have fallen from Mr. Mulvey. I would like to say that coming from the Provinces, as they say in London, I am sure the election of Mr. Carter will be very well received in Lancashire. (Cheers). He has done a great deal of very good local work—I may term it—in Lancashire for the various Societies he has been connected with, and nobody is more respected and more highly honoured in his own town of Burnley—some of you London men may not have heard of Burnley (Laughter)—than he is. Burnley is a large town with a lot of very wealthy people, including my friend Mr. Carter, and great numbers of those people come to London and spend their money. I think under all the circumstances you could not do better than elect Mr. Carter as President for the ensuing year seeing that he possesses qualities very suitable for the position. (Cheers).

Mr. ABSON: Mr. President and Gentlemen, I should like to be allowed to support the proposition. I have known Mr. Carter perhaps longer than any other member round this Board, and I have only known him to respect him. I am sure that if elected to the Presidency of this Council he will fill the chair with honour and dignity to himself and to ourselves. I have very much pleasure indeed in supporting the proposition.

The PRESIDENT: Are there any more nominations? If not I will put the motion—that Mr. Carter be elected President for the ensuing year.

The resolution was then put and carried unanimously.

The PRESIDENT: I declare Mr. Carter elected President for the ensuing year. I wish to offer him my felicitations and to wish him a very happy year of office. (Cheers).

The chair was then vacated by Prof. Mettam, and after Mr. Carter had been decorated with the chain and robe of office he took the chair amid hearty cheering.

The PRESIDENT (Mr. Carter): Mr. Mulvey, Mr. Lawson, Mr. Abson, and gentlemen,—I thank you most sincerely and from the bottom of my heart for the very great honour that you have this day conferred upon me—the greatest honour that this Council has in its power to confer upon any of its members. I do not enter upon this office lightly and without due consideration, knowing as I do the great importance of the office and the responsibility and work which it entails. At the same time I promise you, gentlemen, to give you my best. I will try and uphold the dignity of the chair to the best of my ability, and I hope and trust when the time comes that I have to hand over the badge of office and the regalia to my successor, they will be in as pure a condition as I received them from my predecessor, Prof. Mettam. As you know, gentlemen, preceding me, we have had an exceptionally energetic President. It has been said before, that Professor Mettam during the two years term of his office has traversed something like 10,000 miles in the pursuit of his duty as the President of this College, and I believe he has attended between seventy and eighty meetings. You will readily understand, therefore, that following in the wake of such an able and energetic President makes my task very much the greater. Gentlemen, I thank you sincerely and from the bottom of my heart for the great honour, and I trust that I shall conduct the meetings creditably not only to myself but to this Council, and to the satisfaction of the whole of the profession. There will be nothing wanting on my part to try and make everything go smoothly. At the same time I take courage from the fact that I shall have the able counsel, guidance, and help of every gentleman round

this table. (Hear, hear). I would like before I sit down to express my grateful thanks to every member of this Council for the kindness and courtesy that have at all times been extended to me since I have had the pleasure of sitting at this table, sixteen years. I thank you one and all, gentlemen, for the very great honour you have conferred upon me. (Cheers).

Mr. TRIGGER: Mr. President, in offering you my personal congratulations, which I very sincerely do, upon your election as President, I am going to ask you to accord me the privilege, which I am sure you will do, of proceeding at this stage, without losing one moment, to accord to our ex-President a very hearty vote of thanks for the admirable manner in which he has conducted our proceedings during the past two years. (Cheers). I rise very hastily because I am quite sure that every member of the Council is anxious to occupy the position I at present occupy of proposing the resolution; but I venture to claim that it is my privilege to do so so inasmuch as two years ago I had the honour of proposing that Prof. Mettam should be elected President of the College. Whether or not that suggestion of mine that Prof. Mettam should be elected as President has been justified, I leave it to this Council to say. You have remarked, sir, upon the yeoman service and the great work he has done for the profession. We here know that no man could possibly have behaved in a more whole-hearted manner in the interests of the profession than Prof. Mettam has done. That is infinitely to his credit, and it stands as a record of the amount of work he has done on behalf of the members. We have had the pleasure during the past two years of seeing at our head, a gentleman of influence and position who carried a great deal of weight whenever he appeared to represent the Council. I am sure the veterinary profession recognises the debt of gratitude they owe to Prof. Mettam, and everybody I am sure wishes to pay him the compliment of placing on record not only on behalf of this Council, but on behalf of the profession generally a cordial vote of thanks for the most admirable, dignified, and courteous manner in which he has filled the position of President during his term of office. I move that such a resolution of thanks be placed on the minutes of the Council. (Cheers).

Mr. MULVEY: Mr. Trigger has advanced as one reason for proposing a vote of thanks to Prof. Mettam that he had the honour and pleasure of proposing him as President two years ago. I think that I also have had the honour and pleasure of proposing Prof. Mettam as President, and while I claim to speak on that ground I should like to say how thoroughly I endorse everything that has fallen from Mr. Trigger with regard to the work that Prof. Mettam has done. He has, as Mr. Trigger said, entered whole-heartedly into the work of this Council, and he has not only carried it out to the satisfaction of the Council, but I am perfectly certain that the whole of the members of the profession will recognise the distinguished ability which he has brought to bear on the work. (Cheers).

The resolution was then put and carried with acclamation.

Prof. METTAM, who on rising to reply was very cordially received, said: Mr. President and Gentlemen,—I thank you very much, from the bottom of my heart, for the exceedingly kind expressions that have gone forth from the proposer and seconder of this resolution, and also for the way in which you, Gentlemen, have received it. It has been a great pleasure for me to do what I can for my profession, and if I have in the slightest degree merited this very high eulogy which has been placed upon my services I am more than happy. It was the greatest possible compliment paid to me to be elected President of the Royal College of Veterinary Surgeons. If possible a greater compliment was paid me by re-electing me, and to find that you are satisfied

with what I have done, more than compensates me for any labour it has involved. I can assure you it will be one of the most cherished possessions of my life to find that what I have done has been agreeable to my profession. I thank you very much. (Cheers).

ELECTION OF SIX VICE-PRESIDENTS.

The SECRETARY: The six Vice-presidents last year were Messrs. Bradley, Carter, Lawson, Lloyd, Roberts and Wharam.

Mr. TRIGGER: I move that those gentlemen be re-elected *en bloc*, and that Prof. Mettam take the place as Senior Vice-president of the late Mr. Roberts.

Major-General Thomson, Mr. Clarkson, Mr. Price and Mr. McKinna were also nominated, and Messrs. Lawson, Clarkson and Thomson requested that their names should be withdrawn, Mr. Clarkson saying: Personally I feel rather strongly that the position of Vice-President of this College is a particularly honourable one, and that it is not right that a man who enters the Council should step straight into the Vice-Presidency. I think he should earn that title before he gets into it.

Eventually the following six gentlemen were elected as Vice Presidents: Prof. Mettam, and Messrs. Lloyd, Wharam, Price, McKinna and Lawson.

ELECTION OF TREASURER.

Mr. TRIGGER: I have very great pleasure in moving that Mr. Mulvey be reappointed Treasurer of the College. I cannot imagine that we could possibly think of electing anyone else as long as we have Mr. Mulvey with us. I am sure you will all agree with me that what has been said about Prof. Mettam as President applies equally to Mr. Mulvey as Treasurer. The profession look upon him as their Treasurer. (Cheers).

Mr. MASON: I second the motion. Although Mr. Mulvey keeps on shaking his head at the very miserable condition of our finances I do not think we can do without him.

Mr. LAWSON: I am delighted to support the motion. The resolution was then put and carried with acclamation.

Mr. MULVEY, who was received with cheers, said in reply: I have to thank the members of the Council for re-electing me to this very honourable position. At the same time although it is a very honourable one it is also a very onerous one.

Mr. TRIGGER: Your duties get lighter every year!

Mr. MULVEY: Mr. Trigger has interpolated the remark that my duties will get lighter every year, but I am afraid I cannot look forward to that at present. I hope that in the distant future the funds of this College will be in such a position that the Treasurer will be able to say he is quite willing that money should be spent on anything and everything that is necessary for the advancement of the profession. (Hear, hear). At the present time he is obliged to say "No" to many projects that he would like to see go forward. (Hear, hear).

ELECTION OF SECRETARY AND REGISTRAR.

Prof. METTAM: May I be permitted to propose the re-election of Mr. Bullock as Secretary and Registrar of the College. I have had an intimate acquaintance with the work of Mr. Bullock for the last two years, and I can assure this Council and the profession that we have no more energetic, no more satisfactory and no more enthusiastic servant. It would not be possible to contemplate a more energetic or more enthusiastic servant. Mr. Bullock has the work of this Council and the interests of the profession at his fingers' ends, he knows exactly what to do, and, when occasion arises, he invariably does the right thing. I think this College and the profession are extremely lucky in having such a good Secretary as Mr. Bullock, and in full knowledge I ask you to unanimously re-elect him to the post of Secretary.

Personally I may tell you that I am extremely satisfied—I mean officially—with the work that Mr. Bullock has done and the enthusiasm and energy that he throws into it. (Cheers).

Mr. MULVEY: I must ask to be allowed to second this proposition. I have perhaps been more intimately acquainted with Mr. Bullock during the time that he has been Secretary of this College than anyone else at this Board, and I can only say that in seconding his election I support every word that has fallen from our late President. I know Mr. Bullock's work and worth, that he is wrapped up in the work of the College, that he whole-heartedly carries out all the wishes of this Council and does everything to their satisfaction. (Cheers).

The resolution was then put and carried with acclamation.

Mr. BULLOCK, who was received with cheers on rising to reply, said: Mr. President, Professor Mettam, Mr. Mulvey and Gentlemen, I thank you for my re-election. The kind words which have fallen from Prof. Mettam and Mr. Mulvey make it difficult for me to find suitable words to reply to them, but I am deeply sensible of the honour you have done me, both by the re-election and the manner of the re-election.

This concluded the business of the Meeting of Council.

QUARTERLY MEETING OF COUNCIL.

The President, Mr. J. H. Carter, occupied the Chair and the same members were present as at the Council Meeting.

MINUTES.

The Minutes of the last meeting, which had been printed and circulated, were, on the motion of Mr. Sumner seconded by Mr. Lawson, taken as read and confirmed.

OBITUARY.

The SECRETARY read the Obituary List.

Mr. MULVEY: I rise with feelings of very deep regret to propose that a vote of condolence be sent to the families of two of the late members of this Council, who have left us since our last meeting. Mr. Roberts was present at our last meeting, and his death came very suddenly. He was a member of the Council for several years, and was respected by all with whom he came in contact. Mr. Faulkner was also a member of this Council, and did his duty well while he was with us. I beg to propose that a letter of condolence be sent to the members of their families in their bereavement.

Mr. GARNETT: Mr. President and Gentlemen, I beg to second the proposition of Mr. Mulvey, and to bear out all that he has said. I feel very sorry, as I know you all do, with regard to one of the two who have been mentioned, but perhaps it comes nearer home to me because I was one of Mr. Roberts' old pupils. During the whole time that I knew him I never knew anyone who had the respect of everybody with whom he came in contact in a higher degree than he had. All his old pupils speak as I do of him, and we know better than anyone else the sterling worth of his character. No one ever went to Mr. Roberts for help but it was afforded to him, and this applies not only to members of the profession but also to friends outside the profession. I knew no one who was more universally respected than Mr. Roberts.

The PRESIDENT: I should like to associate myself with this sad task, and to say that I was personally acquainted with both Mr. Roberts and Mr. Faulkner; they were both great friends of mine. I knew Mr. Faulkner for a great number of years, in fact I succeeded him on this Council when he retired. I always found Mr. Faulkner a gentleman, and one who was a

hard worker in his profession—in fact a slave to his profession.

The resolution was then carried in silence, all present upstanding.

CORRESPONDENCE.

The SECRETARY announced that apologies for inability to attend the meeting had been received from Mr. Lloyd, Mr. Barrett and Mr. T. S. Price, the latter of whom was laid up with a badly fractured arm.

The Secretary further announced that letters had been received from Mr. Charles Roberts, Mrs. Hedley, and Miss Bower, thanking the Council for the letters of condolence that had been sent to their respective families.

The Secretary also announced that letters had been received from the Examiners elected at the last meeting thanking the Council for their appointment.

RIGHT OF WAY.

The SECRETARY: I have to report that on the 24th June in accordance with annual custom I passed through the doorway into the Yorkshire Grey Yard in order to maintain the right of way of the College into Yorkshire Grey Yard.

Mr. TRIGGER: I beg to move that that be entered on the Minutes.

Major-General THOMSON: I second that.

The resolution was agreed to.

PRESENTATIONS TO THE LIBRARY.

The SECRETARY announced that the following presentations had been made to the Library since the last Meeting of Council:—

Veterinary Parasitology, by R. H. Smythe, M.R.C.V.S.; Calendar of the College of Preceptors, 1913-1914; Second Report of the Director of Veterinary Research, Department of Agriculture, South Africa; Annual Report of the Bengal Veterinary College and of the Civil Veterinary Department, Bengal, 1911-1912; Reports of the Council and Auditors of the Zoological Society of London for the year 1912; Report of the Veterinary Surgeon to the Corporation of the City of Glasgow for 1912.

Memoirs of the Department of Agriculture in India, Vol. 1, No. 3. U.S. Department of Agriculture: A Study of the Bacteria which survive Pasteurisation; The Life History of *Habronema Muscæ* (Carter), A Parasite of the Horse transmitted by the House Fly; The Action of Arsenical Dips in protecting Cattle from infestation with Ticks; Chemical changes produced in Cows' Milk by pasteurisation; The Care of the Farm Egg.

A Note on some interesting Results following the Internal Administration of Arsenic in Canker and other Diseases of the Foot in Horses, by Major J. D. E. Holmes, M.A., D.Sc., M.R.C.V.S.; *The Rhodesian Agricultural Journal*, April, 1913; *The Bloodstock Breeders' Review*, July, 1913; *The Journal of the Board of Agriculture*, April, May and June, 1913; Orders of the Board of Agriculture and Fisheries; Leaflets of the Board of Agriculture and Fisheries; *Revue de Pathologie Comparée*, April and May, 1913; *The Journal of Comparative Pathology and Therapeutics*, March, 1913; *The Veterinary Journal*, *The Veterinary News*, and *The Veterinary Record* for the quarter.

On the motion of Mr. McKinna, seconded by Mr. Mulvey, a hearty vote of thanks was accorded to the respective donors.

FINANCE COMMITTEE.

Mr. LAWSON read the following report of a meeting of the Finance Committee held on July 4th, 1913, and moved its adoption.

Financial Statement. The Treasurer submitted his financial statement, showing liabilities amounting to £227 17s. 9d., and a balance in hand of £57 16s. 8d. It was resolved that the financial statement be adopted, and that the Treasurer be ordered to pay the liabilities shown, together with cheques for monthly salaries, examiners' fees and expenses, and examination expenses, gas, electric light.

Auditors Report. The auditors submitted their report on the College accounts for the year 1912-13, which was approved.

Mr. MULVEY: May I be allowed to say one word; it is simply on the old lines, that the balance in hand is now very low indeed, £57 16s. 8d. I have simply to tell the Council and the profession that we must have some more money. Before our next meeting we shall require somewhere about £150, and we have only £57 to meet the claims. So that although we hope to be able to carry on until next October, I want the Council to be prepared for giving me authority to sell out a further amount of Consols, which I am sorry to say I shall be obliged to apply for in October next. I say this, sir, because I want to draw the attention of the profession to the fact that they must not find fault with the Council for not carrying out the work that we recognise ought to be done. The reason we cannot do it is—want of funds.

The motion for the adoption of the report was then put and carried unanimously.

REGISTRATION COMMITTEE.

The SECRETARY read the report of a meeting of the Registration Committee held on Thursday, July 3, from which it appeared that nineteen cases were considered by the Committee. In the case of Wilkinson, a member whose name had been removed from the Register, a letter was submitted from Mrs. Wilkinson, but it was resolved that no action be taken. The Solicitor reported that the infringement had been discontinued in the case of "Sal-Vet." The Secretary was instructed to inform two members in a case of advertising that the issue of the circular submitted was a breach of professional etiquette. The report further stated: Information was received to the effect that G. R. Leighton, non-member, had been appointed Veterinary Inspector to the Local Government Board in Scotland. It was resolved to recommend: That the Local Government Board for Scotland be informed that as the appointment in question is a veterinary appointment, it should, in the opinion of this College, have been filled by a veterinary surgeon. The Secretary or Solicitor were instructed with regard to the course of action to be pursued in the remaining cases.

A letter was received from the Secretary of the Pharmaceutical Society of Ireland reporting the prosecution of a registered druggist for the use of the title "Veterinary Chemist," and it was resolved—that the thanks of the Committee be forwarded to the Society for the action taken in the matter.

A letter was received from Capt. Hylton Jolliffe requesting the College to take action with a view to exempting members from any further examination before commencing practice in Canada. It was resolved that no action be taken in the matter.

Letters were received from members whose alleged testimonials were published in Harvey's Horse-Owners' Notebook, stating that the proprietors of the Notebook had in each case undertaken not to repeat the announcement.

Restoration. The Secretary reported that the name of Mr. Lachlan McLean, of Brooklyn, had been removed from the Register in 1907 owing to incorrect information received from the Post Office. It was resolved that the name of Mr. Lachlan McLean be restored to the Register of Veterinary Surgeons.

On the motion of Prof. Mettam the Council then resolved itself into Committee for the purpose of discussing the report; and when the Council resumed its sittings in public it was unanimously resolved, on the motion of Prof. Mettam, that the report of the Registration Committee be adopted, subject to the following amendment in the case of G. R. Leighton:

"Information was received to the effect that Dr. G. R. Leighton, an unregistered person, had been appointed Veterinary Inspector to the Local Government Board in Scotland. It was resolved that a letter be forwarded to the Local Government Board for Scotland strongly protesting, on behalf of this College, against their action in appointing to the office of Veterinary Inspector a person who holds no registrable qualification as a veterinary surgeon.

That the President, with Sir John M'Fadyean and Mr. W. J. Mulvey be appointed a Sub-committee to draw up this letter of protest."

On the motion of Prof. Mettam, seconded by Major-General Thomson, authority was given for the Seal of the College to be attached to the various prosecutions recommended by the Committee.

EXAMINATION COMMITTEE.

Ma. MULVEY read the following report of the Examination Committee, held on July 3rd:

A letter (6/5/1913) was received from Mr. T. H. Greig asking whether women were eligible for the Diploma of the Royal College of Veterinary Surgeons, and the Secretary was instructed to reply that, under the present constitution of the College, the Council has no power to admit ladies to the examinations for the Diploma.

Educational Certificates. Educational certificates numbered 1346 to 1353 were submitted, and, with the exception of No. 1350, were accepted.

On the motion of Mr. McKinna, seconded by Major-General Thomson, the report was adopted.

PARLIAMENTARY COMMITTEE (INCLUDING MILK BILLS SUB-COMMITTEE).

Mr. GARNETT read the following report of a meeting of the Parliamentary and General Purposes Committee held on Thursday, July 3rd:

A letter dated 13/6/13 was received from the Secretary of the Northern Branch N.V.M.A., containing a resolution of thanks for the action taken by the College with regard to the Milk and Dairies Bills.

A letter (21/4/13) was received from the Secretary of the N.E.V.M.A., containing the following resolution: "That the members of this Association consider that the purchase and use of mallein and tuberculin should be confined to members of the medical and veterinary professions."

After discussion, it was resolved that in the opinion of this College, tuberculin and mallein should be standardised, and that the sale and use of both should be restricted to the medical and veterinary professions.

That a copy of this recommendation be forwarded to the Board of Agriculture and Local Government Board.

MILK AND DAIRIES BILLS.

The following reports were submitted by the Milk and Dairies Bills Special Committee:

A meeting of the Milk Bills Special Committee was held at the College, 10 Red Lion Square, on Wednesday, June 4th. Present: Mr. F. W. Garnett in the chair; Sir John M'Fadyean, Prof. Mettam, Mr. Mulvey, and Mr. Thatcher, Solicitor. The minutes of the previous meeting were read and confirmed.

Milk and Dairies Bill. The Chairman reported that revised amendments had been submitted to the Local Government, but that an agreement had not yet been reached as to the form of the words to be adopted. Arrangements had, however, been made with Mr.

Sanderson, M.P., to table the amendments now submitted, and to watch the matter in Committee.

Milk and Dairies (Scotland) Bill. The Solicitor reported the correspondence he had had with regard to the Milk and Dairies (Scotland) Bill, and, after discussion, it was resolved that a deputation consisting of the President, Mr. Garnett and the Solicitor be appointed to attend on the Local Government Board for Scotland, in order to submit the views of the College with regard to the amendments required to be made in the Milk and Dairies (Scotland) Bill.

A meeting of the Milk Bills Special Committee was held at the College, 10 Red Lion Square, on Thursday, July 3rd. Present: Mr. F. W. Garnett in the chair; Messrs. Mulvey and Thatcher. The minutes of the previous meeting were read and confirmed.

Milk and Dairies Bill. The Chairman reported that, after correspondence with the Local Government Board, the following additional clause had been drawn up to amend Section 2, but that at present the matter was still under discussion:

(3) "Where the medical officer of Health entering a dairy for the purpose of this section is accompanied by a veterinary inspector or other properly qualified veterinary surgeon, such inspector or surgeon shall conduct any examination of cattle therein that may be necessary for the purpose of ascertaining whether or not any of such cattle are affected with disease or the nature or extent of any disease affecting such cattle and the veterinary inspector or other properly qualified veterinary surgeon shall on receipt of instructions from the medical officer of health have power to enter any dairy and examine the cattle therein."

Arrangements had been made for Mr. Sanderson to table the above amendment in the House of Commons.

Milk and Dairies (Scotland) Bill. The Solicitor submitted the following report:

"We beg to report that on the 24th instant Mr. F. W. Garnett, Principal McCall, Dr. Bradley, and Mr. George Thatcher attended as a deputation of the Royal College of Veterinary Surgeons to the Local Government Board of Scotland, at the office of the Board in Edinburgh, and were received by Sir George McCrae, Vice-president; Mr. Ewan F. Macpherson, advocate; Dr. Leslie Mackenzie, medical member; and the Secretary and Assistant Secretary. The deputation was introduced by Sir Robert Wright, of the Board of Agriculture of Scotland. Mr. Thatcher stated the present legal position and what had taken place with regard to the English Bill, and Mr. Garnett and Dr. Bradley then stated the reasons why the proposed amendments were considered necessary. The Vice-president of the Board and the Medical Officer then stated that the Board saw no objection to the veterinary surgeon being the person to examine the cows, and they also considered that it was not unreasonable that he should do so in the absence of the Medical Officer but by his authority. Dr. Mackenzie said that it must be perfectly understood that if the Medical Officer at any time wished to examine an animal with a view of seeing whether it had been the means of conveying human disease, he was not to be precluded from doing so. The details were then discussed, and the Board was willing to recommend the insertion of the following clause after sub-section 2 of section 15, and they suggested that the proposed amendment in sub-section 1 might be omitted, but left this open for consideration:

(3) Where the Medical Officer of Health entering a dairy for the purpose of this section is accompanied by a veterinary inspector or other properly qualified veterinary surgeon, such inspector or surgeon shall conduct any examination of the cattle therein that may be necessary for the purpose of ascertaining whether or not any of such cattle are affected with disease or the nature or extent of any disease affecting such cattle, and the

veterinary inspector or other properly qualified veterinary surgeon shall on receipt of instructions from the Medical Officer of Health have power to enter any dairy and examine the cattle therein.

The Board also suggested that the College should draft some instructions as a guide to veterinary inspectors in carrying out the objects of the Bill, to be submitted for the approval of the Board.

Arrangements had been made for Mr. Price, M.P., to table the above amendment in the House of Commons.

It was resolved that the above reports be adopted.

Dogs (Protection) Bill. It was reported that this Bill was now at its second reading. And it was resolved "That a Sub-committee consisting of the Chairman, Sir John M'Fadyean, and the Solicitor be appointed to watch this Bill, with power to act."

Interpretation Bill. The new Interpretation Bill was submitted, in which it was found that the clauses relating to the Royal College of Veterinary Surgeons were in proper form.

Other Bills. The Protection of Animals (overloading of horses) Bill, and the Docking of Horses Bill, were also submitted.

Mr. GARNETT: I should like, before the reports are adopted, to say a word or two with reference to these Bills, because they have raised a great deal of controversy and discussion among the veterinary surgeons of the country generally; in fact I do not know two Bills which have been introduced into Parliament which have affected the profession as much as these two. You will remember that at the last Council I gave the assurance that when the time came, we would ask the profession to act as one body with regard to the Bill. Owing to the way we have been met by the Local Government Boards of England and Scotland there is no reason now to take any individual action. If the Bills are dropped for this Session they will be most probably introduced again, and then these clauses will be introduced into the new Bills. At any rate there is nothing more for us to do but to see that these amendments which you have accepted to-day are inserted in the Bill when it comes to the Committee stage. We have Mr. Sanderson acting for us with regard to the English Bill, and Mr. Price, of Edinburgh, with regard to the Scotch Bill, and with their assistance I think we may as a profession, feel perfectly safe in our position. (Hear, heard.)

On the motion of Principal McCall, seconded by Major General Thomson, the report was adopted.

HONORARY ASSOCIATES COMMITTEE.

Prof. METTAM read the following report of a meeting of the Honorary Associates Committee held on July 3rd.

Honorary Associates. The names of several gentlemen were submitted and considered. The further consideration of the matter was, however, deferred until the next meeting.

On the motion of Prof. Mettam, seconded by Mr. Lawson, the report was adopted.

BYE-LAWS SPECIAL COMMITTEE.

Mr. GARNETT read the following report of the Bye-laws Special Committee held on Thursday, 3rd July, 1913, and moved its adoption:—

Chairman. It was resolved that Mr. Garnett be appointed to the Chair.

Bye-Laws. It was resolved to recommend the adoption of the following Bye-laws, in accordance with resolution 17 of the meeting of Council, April 11th, 1913:—

"Students holding a diploma for a Degree in Arts, Science or Medicine of any University in the United Kingdom, or the diploma of Member or Licentiate of the Royal College of Surgeons and of the Royal College of Physicians, are exempted from attendance at the first year's course of lectures, and from the examination at

the end of that year, provided that each student so exempted shall be examined in the whole subject of Anatomy, in the Class B. examination."

"Applications from candidates possessing similar qualifications granted by colonial or foreign licensing bodies shall submit their certificates to the Examination Committee, who shall report to the Council as to the eligibility of the applicant for exemption or otherwise."

Mr. MULVEY seconded the motion.

Mr. SHARE-JONES: I was going to propose that as this is a matter of such vital interest, the Report be circulated to the members of Council and come up for discussion at the next meeting. I may be wrong, but if I interpret the Report correctly, you are proposing to exempt graduates in Arts from our first Professional Examination. Is that right? This is a very important matter, the most important matter we have had before us for a very long time. I move, therefore, that the Report be circulated to the members of Council and that it come up for discussion at our next meeting.

Sir JOHN M'FADYEAN: In any case it has to be suspended for three months, but I agree absolutely with Mr. Share-Jones. The question is whether we should not have this amended now, so that it may be suspended at once. If so I will support Professor Share-Jones if he will move that the word "Arts" be deleted, because it is obvious there are so few graduates in Arts who have attended courses in Biology and Chemistry that I really think we might leave them out without any hardship. You cannot possibly give our Diploma to a man who has had no instruction and has passed no examination at all in such fundamental subjects as Chemistry and Biology. I feel that I have no right to say anything on the subject because I ought to have been present at the Committee Meeting. Most unfortunately that was absolutely impossible, but I hope the Council will agree that it would really be better now to delete the word "Arts."

Mr. SHARE-JONES: Do not you think the case would be better met by the insertion in the Regulations of something to the following effect, that we exempt students who have already passed an examination in the corresponding subjects of the first year so far as it applies to Biology and Chemistry in any University or other examining body recognised by this Council in the British Isles, on the principle that any University exempts candidates who have already passed examinations in the corresponding subjects in other Universities? I think it is rather an injustice to a man who comes up for his Inter-Bsc., who has done all the Biology and all the Chemistry that he is ever likely to do so far as his Degree is concerned, that we should demand that he should go on to his Final for his B.Sc. before exempting him from his First Professional.

Sir JOHN M'FADYEAN: I think that is quite right.

Mr. SHARE-JONES: I would be prepared to move a resolution definitely at our next meeting on the subject, but I am not prepared to get up on the spur of the moment and frame such a resolution. It strikes me there are several very grave errors in the Report as it stands.

Prof. METTAM: I do not altogether agree with what Prof. Share-Jones has said. I do not think we should recognise any part of a Degree at all. It is the thin end of the wedge towards allowing men who have taken different courses in other Institutions to come and demand that we should recognise them. The resolution as read by Mr. Garnett speaks of graduates in Arts, Science and Medicine as well as Licentiates of the Colleges of Surgeons and Physicians, and I think at the present time at any rate it can only be expected that we shall give these men grace. I do not think that any man who has gone through a portion of a course in some other branch of science can legitimately claim that we should recognise that portion.

Mr. SHARE-JONES: It is done every day.

Prof. METTAM: In my judgment we should only accept these subjects when they have been part and parcel of his Degree Examination. The only amendment which I personally would suggest to the resolution is that as regards the Degree in Arts it should be necessary that it should include the subjects which we include in our first Professional. It is possible for a man to take a Degree in Arts including Botany, Chemistry, Physiology and other subjects, and I think if the Degree in Arts includes Biology and Chemistry, a man with such a Degree could claim to be exempted exactly as a man can with a Degree in Science or in Medicine.

Mr. SHARE-JONES: In view of the discussion I shall adhere to my proposition as a matter of fairness, that this important matter should be circulated to the members in order that they may come prepared with material for discussion at our next meeting. It is certainly too important a matter in my humble judgment, to be dismissed with a few moments' discussion such as we can have this afternoon.

Prof. METTAM: May I interpose just for a moment? This is only the Report of the Committee. Surely we can accept the Report and have it suspended on the board, and then it is open to Prof. Share-Jones or any other member of the Committee to amend it.

Prof. SHARE-JONES: I have just been informed by an old member of this Council that if it is suspended on the board I can simply move a negative to the whole thing; it cannot be amended. I am supporting the principle of freedom of discussion, that because a Report comes up from a Committee it does not signify that that Report must go through according to the laws of the Medes and Persians. That Report is placed before the Council to be discussed, and it is in order that we may have free discussion that I am asking that the Report may be circulated. It is the most important Report we have had for some long time, and I think every individual member of Council has a right to demand that important material of this kind should be circulated before it is discussed. I should like to correct Prof. Mettam in what he has said. We will take our friend Dr. Bradley. If Dr. Bradley takes a Degree in Science, he has not to pass an examination in the intermediate Science subjects again if he wishes to proceed to a Degree of Medicine where those subjects come in the curriculum. That is an axiomatic principle underlying the course of studies at all the Universities. If a man pass in a subject in one University, the students are not required to pass the same subject in another University.

Sir JOHN M'FADYEAN: In the same University. That is the difference.

Prof. SHARE-JONES: It is covered by the principle which underlies exemption, and that principle of exemption is being extended more every day, through an understanding which has been arrived at between the various Universities for the purpose of economising the time of the student.

Sir JOHN M'FADYEAN: I will put myself in order by moving this resolution: "That the matter be referred back to the Committee with instructions that they will so amend it as to give exemption to graduates in Arts who have passed in biology and chemistry." Although I admit that that there is some force in what Prof. Share-Jones says, I do not agree with him that we ought to exempt any candidate on the ground merely that he has passed some particular examination in biology or in chemistry. I agree with Prof. Mettam that we ought only to give exemption to those who have actually graduated. I may point out to Prof. Share-Jones—he will correct me if I am in error—that it was specially remitted to this Committee to frame a bye-law that would give exemption to graduates, not to undergraduates. The particular cases that Prof. Share-Jones referred to are cases in which a University, which

has examined its own students in a particular faculty; will allow them to proceed to an examination in another faculty without requiring them to be re-examined in the subjects that they have already passed in; but I am not aware that there is any University which will exempt from examination a candidate for its degree on the ground that he has already passed in that subject at another University. [Prof. Share-Jones: Oh yes]. If I am told that there are such cases I am still not convinced. I shall be prepared to support Prof. Share-Jones when he will come and show us that there are Universities who will accept our examinations in chemistry and biology although the student has not graduated. It is a case clearly for reciprocity. If there is any University which will accept our examination in biology and chemistry, independently of whether the candidate has taken the diploma or not, then I think it would be fair to give a similar concession to the University. In the meantime I think we can quite well defend our position in restricting the concession to those who have actually taken a degree. I move that this be referred back.

Prof. SHARE-JONES: I was asked to state if I knew a case of a University in which it was done.

Sir JOHN M'FADYEAN: I did not ask for it; I said I did not know of any; but it does not affect my position for the reason stated.

Mr. WHARAM: I beg to second that.

Mr. GARNETT: I am quite willing on behalf of the committee to accept Sir John's amendment that it be referred back to the Committee to make that addition with regard to the Arts degree. But I would point out, Sir, most strongly that the reference to this Committee was distinct and definite. It read as follows, and if Prof. Share-Jones had only read the reference, he would see that we could not possibly go into the matters which he has raised to-day: "That the bye-laws Special Committee be re-appointed with instructions to formulate bye-laws to exempt graduates in science and arts from the first professional examination, and the conditions of such exemption, and to report." If Prof. Share-Jones had any objection to that resolution, which he had not at the last meeting, the last meeting of this Council was the proper time to have raised them. The Committee would have been exceeding its reference if it had gone into any other question, excepting into granting exemption to graduates and no others. I accept on behalf of the Committee the amendment of Sir John M'Fadyean.

Prof. SHARE-JONES: I move that the Committee be empowered also to consider—they need not recommend if they do not care to make the necessary investigation—the advisability of exempting students who have passed any one of the Universities of the British Isles in the subjects of the intermediate.

The PRESIDENT: I am afraid that is out of order.

Prof. SHARE-JONES: That will come as an additional proposition, otherwise I shall have to vote against this proposition.

The SECRETARY: The resolution as suggested by Sir John M'Fadyean is: "That the report be referred back to the Committee with instructions that they will so amend it as to give exemption to those graduates in Arts who have passed in the subjects of biology and chemistry."

The resolution was then put and carried.

Prof. SHARE-JONES: I should also like to move that the Committee shall consider the advisability of exempting students who have passed the intermediate examination in science in those subjects at any recognised University in the British Isles. I move that now because it will relieve me from future attacks, such as the one I have already had from Mr. Garnett this afternoon, if I care to enter into the matter at our

next meeting. I may say it is an accepted principle that I am asking this Council to adopt. I can name a student connected with myself who passed the intermediate examination in law at the University of London. The student comes to our University; he is not asked to pass the intermediate examination in law again; he is permitted to pass on to the final examination for the degree. It is a matter of economy of time. With reference to the report which Mr. Garnett referred to, you practically ask the student to put in seven years to qualify. Is it not sufficient for a student to pass on to the intermediate in those subjects? Anyway, this is a matter which will come up for discussion, if my proposition is seconded, at our next meeting. I beg to move that the Committee take into consideration the question of exempting students who have passed the intermediate examination in science in those subjects.

Mr. SUMNER: I second that resolution.

Mr. GARNETT: I should like to speak against that proposition. I really think it is one that we should not accept. As far as my recollection goes, the decision of the Special Committee which sat and reported on this subject was to ask us to exempt persons holding certain degrees. I entirely agree with what Prof. Mettam said in regard to it, that we should not throw ourselves open to any man who just passes part of a degree course. It is throwing the portals open far too wide. We are extending them now very much wider than they have ever been before, when these things get properly carried out. Besides, as I pointed out at the last meeting of Council, they accepted the principle that we should not go further than to exempt persons holding certain degrees, and it is going back altogether on what we have already passed.

Sir JOHN M'FADYEAN: May I be allowed to point out that there is a very material difference between getting exemption for those who have passed the examination in biology and chemistry and then proceeding to the full degree, and giving exemption to those who, having entered for a particular degree and passed in biology and chemistry, abandon the pursuit of the degree. I am prepared to maintain that the student who has spent his first year in studying medicine or science and passes those subjects, and then comes to us under this exemption, if we extended it to him, and passes only three years in studying veterinary medicine at a Veterinary College, is probably at the end not so good a man as a man who has spent four years at a Veterinary College. But I think we should probably all be ready to admit that it would be desirable to entice into this profession those who have already taken a degree in Arts or in science, and it is on that ground that we offer that exemption to them.

Prof. SHARE-JONES: (Cries of "Vote, vote.") I have a perfect right to reply according to the ordinary rules of discussion. All my proposition means is that we are simply asking them to consider it.

Prof. SHARE-JONES' proposition: "That the Committee be instructed to take into consideration the question of exempting students who have passed the intermediate examination in science" was then put and lost.

PRELIMINARY EXAMINATION COMMITTEE.

Principal McCALL read the following report of a meeting of the Preliminary Examination Committee held on Wednesday, June 4th, 1913:—

Preliminary Educational Examinations. The Secretary submitted a memorandum showing the effect of the resolutions of the General Medical Council with regard to Preliminary Educational Examinations, and also giving statistics as to the number of veterinary students taking the respective examinations.

After consideration it was resolved to adjourn the meeting until July.

Principal McCALL also read the following report of a meeting of the Committee held on July 3rd, 1913 :—

Preliminary Examination. The Secretary submitted the new regulations of the General Medical Council with regard to preliminary medical examinations, which provide for the general raising of the standard of marking, while permitting the examination to be taken at not more than two sittings. It was resolved to recommend :—

(a) That candidates presenting themselves for the first professional examination in and after December 1915, be required to produce a certificate of having passed one of the preliminary educational examinations in accordance with the revised regulations of the General Medical Council.

(b) That Schedule 1 be revised in accordance with the above recommendation.

(c) That the following examining bodies be requested to continue to examine veterinary students on the standard at present recognised, up to and including the examination to be held in September, 1914 :

The College of Preceptors : Preliminary examination for medical students.

Educational Institute of Scotland : Preliminary medical examination.

Intermediate Educational Board of Ireland : Middle grade examination.

On the motion of Principal McCALL, seconded by Mr. McKINNA, the reports were adopted.

LIBRARY AND MUSEUM COMMITTEE.

The PRESIDENT read the following report of a meeting of the Library and Museum Committee held on Friday, July 4th, 1913 :—

Presentations to Library. It was resolved to recommend "That in future the list of presentations to the library be submitted in the first instance to the Library and Museum Committee.

Purchase of Periodicals. It was resolved that the Bulletin of Tropical Medicine and the Tropical Veterinary Bulletin be obtained for the use of the library at a cost of one and a half guineas per annum.

The question of the purchase of other periodicals to complete the collections in the library was considered, but it was found impossible on financial considerations to make any recommendation.

Use of Library. It was resolved "That under existing circumstances no books be allowed to leave the library, but that the library be open for reference to Members, and also to non-members on presentation of a letter of introduction from a Member.

Catalogue. The necessity for the preparation of a card index catalogue was discussed, but on financial grounds the matter was not proceeded with.

The PRESIDENT : I move the adoption of the report.

Mr. MULVEY : I second that.

Mr. McKINNA : It is a pity that the books are not to be loaned. I should like to know the reason which prompted the Committee to bring in such a resolution as this.

Prof. METTAM : Until the funds of the College permit it, the library can be only considered a reference library and not a circulating library. If it was to be run as a circulating library it would mean an additional expense, which we cannot at present afford.

Mr. McKINNA : I think it is a pity that a library of the character that we have at this College should not be available as a circulating library, at least to Members of the Council.

Mr. MULVEY : The Members of the Council have no right to any privilege that the ordinary Members of the College do not possess.

Mr. McKINNA : I mean in the wider sense. I do not see why, unless the Committee brings in some serious

reason for it, at this stage of the day, they should all at once make this proposition.

Sir JOHN M'FADYEAN : I will suggest a reason which you may find sufficient, and that is that if the library is to be made a circulating library, it would require the services of a librarian. The mere undertaking personally to return the books is not enough. The issue and return of books must be controlled. We should have to appoint a librarian to do that, and we cannot afford it.

The motion for the adoption of the report was then put and carried.

FELLOWSHIP DEGREE COMMITTEE.

Prof. METTAM read the following report of a meeting of the Fellowship Degree Committee held on July 4th, 1913 :—

Revision of the Fellowship Regulations. It was resolved to recommend : That in order to enable existing members to sit for the Fellowship Examination under the present regulations, the said regulations be continued in force for five years after the introduction of the suggested new regulations.

That new Regulations be instituted forthwith as follows :—

Qualification Period. Two years after Membership. *Thesis.* A Thesis to be submitted on the results of original research or observation, on one of the following subjects : Anatomy, including Surgical Anatomy ; Physiology ; Pathology, including Bacteriology and Protozoology ; Helminthology and Entomology ; Pharmacology and Toxicology ; Medicine ; Tropical Medicine ; Surgery ; Sanitary Science and Administration (open only to holders of the Diploma in Veterinary State Medicine).

Examination. The Candidate shall be examined orally on the subject matter of his thesis, and may, at the discretion of the Examiners, be examined practically or by written papers in that branch of Veterinary Science to which the subject of the thesis belongs.

The subject or subjects of examination to be shown on Diploma.

Regulations for New Diploma. It was resolved to recommend that the following regulations be instituted :—

Title. Diploma in Veterinary State Medicine.

Qualification Period. Twelve months after membership, including at least : Six months' practical instruction in Meat Inspection, Hygiene of Byres, Stables and Markets under Veterinary Inspectors or Teachers recognised for that purpose by the Royal College of Veterinary Surgeons ; A further period of six months' attendance at approved courses of instruction on the following subjects at an affiliated School : Epizootiology, Veterinary Hygiene and Toxicology, Veterinary Bacteriology and Protozoology, Chemistry as applied to Veterinary Hygiene.

Examination. Written and Oral : Epizootiology ; Veterinary Hygiene, including Meat and Dairy Inspection, Sanitary Laws, Administration and Reporting, and Toxicology ; Veterinary Bacteriology and Protozoology.

Supplementary Charter. It was resolved to recommend that the following powers be sought in a new Supplementary Charter : To reduce the period between Membership and Fellowship Examinations, To institute a new Diploma in Veterinary State Medicine, To approve Teachers, appoint Examiners, and make bye-laws, To hold the Annual General Meeting on any of the first seven days in the month of June.

That the preparation of the new Supplementary Charter be referred to the Parliamentary Committee.

That in view of the urgency of the matter, it is undesirable that any subject of a contentious nature should be introduced into the draft Charter.

Prof. METTAM : I propose that the Report be adopted.
Sir JOHN M'FADYEAN : I second that.

Mr. SUMNER : As a further instruction to the Fellowship Committee, Mr. Trigger, who has unfortunately had to leave the meeting, left a suggestion that we should move an instruction to the Charter Committee to put a Clause in to the effect that there shall be two Vice-presidents instead of six. Last year one member who had been on the Council only two years was appointed a Vice-president, and he is reappointed this year ; and one gentleman to-day who has only been on the Council one year declined the offer of the position. Mr. Trigger is of opinion that six Vice-presidents are certainly more than are required, and that if the office was confined to two it would confer a greater honour than it does now with six. On Mr. Trigger's behalf I suggest that an instruction be made to the Charter Committee that the number of Vice-presidents of the College be reduced from six to two.

Mr. CLARKSON : I should like to second that instruction. I think if we have only two Vice-presidents, it will be something more of an honourable position than it is at present with six, and when we practically hawk the post about.

Mr. SUMNER : I do not think it is likely to be a contentious matter.

The motion for the adoption of the Report, together with Mr. Sumner's suggestion, was then put and carried unanimously.

EXAMINATION SYLLABUS COMMITTEE.

Dr. BRADLEY presented the following report and recommendations of the Examination Syllabus Committee :

THE SECOND SCHEDULE.

Syllabus of Subjects for Professional Examinations.

Examination A.

(1) ANATOMY OF DOMESTICATED ANIMALS.

Bones, Ligaments, and Joints of the Horse, Dog, Ox, Sheep, and Pig. The student will also be expected to possess a general knowledge of the skeleton of the Cat and Fowl.

(2) CHEMISTRY AND ELEMENTARY PHYSICS.

Elementary Physics.—Mass, Weight, Diffusion of liquids and gases, the Air-pump, the Barometer, Boyle's Law, the Principles of Archimedes, Special gravity of liquids and gases, Thermometers, Expansion of gases and liquids by heat, Charles' law, Avogadro's hypothesis, Convection, Winds, Ventilation, Conduction of heat through solids, Ebullition, Evaporation, Dew point, Specific and latent heat, Radiation, Metric system, Elementary facts regarding magnetism and electricity, Dispersion of light by a prism.

Chemistry.—Experimental study of chemistry of air and water, Laws of chemical combination, Equivalents, Combining weights, Symbols, Formulæ, Equations, the Atomic theory, Vapour density, Molecular weights. Chemical study of Oxygen, Ozone, Hydrogen peroxide, Chlorine, Hydrochloric acid, Chloride of lime, Hypochlorites, Chlorates, Bromine, Hydrobromic acid, Iodine, Hydriodic acid, Nitrogen, Nitrous oxide, Nitric oxide, Nitric peroxide, Nitrous acid, Nitric acid, Ammonia, Carbon and its oxides, Sulphur and its oxides, Sulphurous and sulphuric acids, Sulphuretted hydrogen, Phosphorus—its oxides and chlorides, Phosphorous and phosphoric acids, Phosphoretted hydrogen. Silicon, Silica, Silicic acid, Boron, Boric acid, Arsenic—its oxides and chlorides, Arsenious and arsenic acids, Arseniuretted hydrogen, Radium. Study of the following metals and of their more important combinations : Potassium, Sodium, Magnesium, Calcium, Zinc, Iron, Manganese, Aluminum, Chrom-

ium, Antimony, Lead, Copper, Bismuth, Mercury, Silver. Determination of the Hydrogen, Carbon, and Nitrogen in organic bodies. Study of the paraffins : Ethylene, Acetylene, Benzene, Nitro-benzene, Phenol and its more important derivatives. Structure of flame: Coal gas. Methyl and Ethyl Alcohols : Chloroform, Chloral, Iodoform, Glycerine, Ethereal salts, Formic and Acetic aldehydes, Ethylic oxide, Formic, acetic, tartaric, oxalic, lactic, citric, benzoic, and salicylic acids. Cyanogen, Hydrocyanic acid, Urea, Uric acid, Cane sugar, Grape sugar, Milk sugar, Starch, Dextrin, Glycogen, Cellulose. Albumen, Casein, Gelatine. Fats : Saponification, Glycerine. Morphine, Quinine, Strychnine. Fermentation : Alcoholic, acetic and lactic.

Practical Examination.

Candidates may be asked to identify any of the inorganic, basic, or acid radicles in the above list, and of the following organic compounds : Starch, Sugar, Albumen.

(3) BIOLOGY.

Biology. General Principles of Biology.

Botany. (i) *The Vegetative Organs of a Flowering Plant.*—Root, Stem, Leaf. The Morphology and modifications of roots and stems. Buds and branching. Different kinds of leaves. Modifications of foliage leaves. The Histology* of root, stem and leaf. Formation of lateral members. Growth in thickness of root and stem.

(ii) *The Plant Cell.** Protoplasm and other cell contents. The cell wall and its modifications. Cell division. Tissues and tissue systems.

(iii) *The Inflorescence and the Flower.* Definite and indefinite inflorescences. Parts of a flower. The structure and development of the ovule.

(iv) *Fertilisation and the Fruit.* Pollination and Fertilisation. Different kinds of fruits. The seed and its germination. Dispersal of seeds and fruits.

(v) *Plant Functions.* The composition of plants. Essential food substances. Water cultures. Gaseous and liquid absorption. Movement of water in plants and transpiration. Photosynthesis. The absorption of nitrogen. Destructive metabolism and respiration. Conditions for growth. Simple movements in plants. Exceptional modes of nutrition.

(vi) *The Principles of Classification.* Monocotyledons. Dicotyledons. Characters of the following families : Gramineæ, Liliaceæ, Ranunculaceæ, Papaveraceæ, Cruciferae, Rosaceæ, Leguminosæ, Umbelliferae, Labiatae, Solanaceæ, Scrophulariaceæ, Compositæ.

Elementary facts regarding ferns, algae, and fungi.

Zoology. (i) *Protozoa* : General features. Amœba. Trypanosoma. Pyroplasma, and Coccidium.

(ii) *Cœlenterata* : Hydra.

(iii) *Annelida* : Lumbricus and Hirudinea.

(iii) *Nematoda, Platyhelminthes* : Chief characteristics of Ascaris, Distomum hepaticum, Tania solium, T. echinococcus.

(v) *Arthropoda* : Main characteristics of the phylum, and distinguishing features of its sub-divisions: Crustacea, Myriapoda, Insecta, Arachnida.

(vi) *Vertebrata* : Main morphological features. Characters of the classes, Pisces, Amphibia, Reptilia, Aves, Mammalia. Distinguishing features of the orders of Mammals. Sub-divisions of the Orders Carnivora and Ungulata.

In the Oral part of the examination, candidates will be expected to be able to identify and classify examples of the types dealt with in the syllabus.

* Including only such of the microscopic structure of plants as is necessary for the understanding of their function.

Examination B.**(1) ANATOMY OF THE DOMESTICATED ANIMALS.***

Candidates will be required to show a knowledge of the entire anatomy of the horse. In the case of the other domesticated animals the examination will extend to the viscera, and to the salient features of the muscular, vascular, and nervous systems compared with the corresponding parts of the horse.

(2) HISTOLOGY AND PHYSIOLOGY.

Histology of the Domesticated Animals, including simple histological methods.

Physiology of the Domesticated Animals.

Candidates will be expected to be familiar with the characteristic chemical relations of albumen and sugar, and with the elementary chemical examination of milk, bile, and urine.

(3) STABLE MANAGEMENT, AND MANIPULATION OF DOMESTICATED ANIMALS. PRINCIPLES OF SHOEING HEALTHY ANIMALS.

Approaching animals : Securing animals in stables : Handling animals : Handling special parts—head, foot, tail, etc. : Use of twitches, muzzles, rings : Grooming—tools and implements : Clothing—Bandaging : Clipping—Singeing : Halters—Pillar-reins : Adjusting saddles, bridles, collars, etc. : Principles of shoeing sound feet.

Examination C.**(1) PATHOLOGY, BACTERIOLOGY, AND PROTOZOLOGY.**

General Pathology : Special Pathology : General Bacteriology and Protozoology : Special Bacteriology and Protozoology of the diseases of the domesticated animals : Immunity.

(2) MATERIA MEDICA AND TOXICOLOGY.

Forms in which medicines are used. Methods of administration or application. Actions, uses and doses of medicines. Classification of medicines. Special and synthetic preparations, their actions, doses, and derivation. Incompatibles. Impurities. Serum Therapy. Poisons, organic and inorganic. Symptoms and post-mortem appearances of poisoning. Antidotes, chemical and physiological. Tests. Writing and reading prescriptions.

There will be a practical examination in Pharmacy.

(3) VETERINARY HYGIENE AND DIETETICS.

Water—quality, quantity, impurities, tests. Air—quality, quantity, impurities. Site, Construction, Ventilation, Heating, Drainage. Fittings of : Stables, Cowsheds, Kennels, Pigsties, Sheep-pens. Disposal of excreta. Foods—grasses, cereals, roots, etc. Feeding—principles, quantities, varieties of foods, nutritive values, preparation and mixing food. Dipping and spraying animals. Preparations employed. Breeding and Heredity. Hygiene of Gestation and Milk Production. Dairies, Cowsheds, and Milkshops, Orders and Regulations. Recognition of defects in buildings. Recognition of defects in food stuffs. Transport of animals. Disposal of carcasses. Disinfection and disinfectants.

Examination D.

(1) Principles and Practice of Veterinary Medicine, and Meat Inspection.

(2) Principles and Practice of Veterinary Surgery and Obstetrics (including Examinations as to Soundness).

ALTERATIONS TO BYE-LAWS.

The Committee also recommended that the following consequential alterations should be made in the bye-laws :—

* *i.e.* Horse, Dog, Ox, Sheep, Pig, Cat, and Fowl.

Bye-law 53 (New number 62) : Add the words "healthy animals" after "principles of shoeing."

Bye-law 54 (New number 63) : In section (a) line 2, add the words "and protozoology" after the word "bacteriology." In section (b) line 3, add the words "and protozoology" after the word "bacteriology." In section (c) delete the word "Therapeutics."

Bye-law 67 (New number 76) : In examination B, subject 3, add the words "healthy animals," after "Principles of Shoeing." In examination C, subject 1, replace the words "Morbidity, pathology, bacteriology," by the words "Pathology, bacteriology and protozoology." Subject 2, delete the words "Practical pharmacy, therapeutics," and add, in the line 2, after "minutes," the words "including a practical examination in pharmacy."

On the motion of Dr. Bradley, seconded by Mr. Sumner, the report was adopted.

ELECTION OF AUDITORS.

On the motion of Mr. McKinna, seconded by Mr. Slecock, Messrs. Woodhouse and Wilkinson were re-appointed auditors for the following year.

DATES OF COUNCIL MEETINGS AND EXAMINATIONS.

The following dates for Committee and Council meetings and examinations were unanimously agreed to :—

DATES OF COMMITTEE AND COUNCIL MEETINGS.

1913 : October 9th and 10th. 1914 : January 8th and 9th ; April 2nd and 3rd (Good Friday, April 10th) ; Annual General Meeting, June 3rd ; July 2nd and 3rd.

DATES OF EXAMINATIONS.

1913 : Written, December 8th ; Orals, December 9th, Dublin ; Glasgow, Edinburgh, Liverpool, London. 1914 : Written, July 6th ; Orals, July 7th, London, Edinburgh, Glasgow, Liverpool, Dublin.

Fellowship Examination.—December 6th, 1913 ; May 16th, 1914.

Walley Memorial Examination.—October 4th, 1913.

APPOINTMENT OF COMMITTEES FOR THE YEAR.

The following Committees were appointed :—

Registration Committee.—The whole Council.

Examination Committee.—Messrs. O. C. Bradley, J. Dunstan, F. T. G. Hobday, J. S. Lloyd, J. McCall, J. McL. McCall, A. E. Mettam, Sir J. M'Fadyean, J. McKinna, W. J. Mulvey, J. T. Share-Jones, E. S. Shave, W. Shipley, S. H. Slecock, Sir S. Stockman, H. Sumner.

Finance Committee.—Messrs. J. Abson, O. C. Bradley, J. Clarkson, F. W. Garnett, A. Lawson, J. S. Lloyd, J. McKinna, A. W. Mason, W. J. Mulvey, A. E. Mettam, W. Packman, W. Shipley, H. Sumner, R. C. Trigger, S. Wharam.

Parliamentary and General Purposes Committee.—Messrs. J. Abson, W. F. Barrett, O. C. Bradley, W. Burt, J. Clarkson, F. W. Garnett, A. Lawson, Sir J. M'Fadyean, A. W. Mason, A. E. Mettam, W. J. Mulvey, T. S. Price, J. T. Share-Jones, Sir S. Stockman, H. Sumner, H. Thomson.

Annual Fee Committee.—Messrs. W. F. Barrett, O. C. Bradley, F. W. Garnett, J. McCall, Sir J. M'Fadyean, A. W. Mason, A. E. Mettam, W. J. Mulvey, W. Packman, H. Sumner, H. Thomson, R. C. Trigger.

Library and Museum Committee.—Messrs. J. Abson, G. A. Banham, O. C. Bradley, W. Burt, J. Dunstan, F. T. G. Hobday, Sir John M'Fadyean, W. J. Mulvey, J. McKinna, A. E. Mettam, J. S. Lloyd, J. T. Share-Jones, E. S. Shave, S. H. Slecock, S. Wharam.

Publication Committee.—Messrs. J. Abson, W. Burt, J. McCall, J. McL. McCall, Sir J. M'Fadyean, W. J. Mulvey, T. S. Price, R. Pringle, A. E. Mettam, W.

Packman, J. T. Share-Jones, Sir S. Stockman, S. Wharam.

Steel Memorial Committee.—Messrs. J. Abson, G. A. Banham, O. C. Bradley, J. McCall, Sir J. M'Fadyean, A. E. Mettam, W. J. Mulvey, H. Sumner, R. C. Trigger.

Honorary Associates Committee.—Messrs. G. A. Banham, O. C. Bradley, A. Lawson, J. McCall, A. E. Mettam, Sir J. M'Fadyean, R. Pringle, Sir S. Stockman.

The President is *ex-officio* member of all Committees.

NOTICES OF MOTION.

Prof. METTAM: I beg to give notice of suspension of the second Schedule, syllabus of subjects for professional examinations. I give notice that I will move that these be adopted as the bye-laws at the next meeting of Council.

I also beg to give notice that I shall move the alterations with reference to the proposed changes in the Fellowship examinations and the regulations for the new diploma. Also the following resolution:—"That candidates presenting themselves for the first professional examination in and after December, 1915, be required to produce a certificate of having passed one of the preliminary educational examinations in accordance with the revised regulations of the General Medical Council."

Sir JOHN M'FADYEAN: I do not know that this is the time to offer any objection to this proposed alteration of bye-laws, but I may say now that when it comes up I shall feel obliged to oppose that because the language is not precise enough. What are "the revised regulations of the General Medical Council?" We must remember that before 1915 the General Medical Council may revise its bye-laws half-a-dozen times, and I think some other phraseology will have to be found to give effect to what we have in view. I object as a matter of principle to putting in our bye-laws that we are bound by the bye-laws of any other body. I think we must preserve the present form of our bye-laws, that is to say we will accept certificates specified in the Schedule annexed to the bye-laws. There is plenty of time to effect the alteration.

Prof. METTAM: The notice I give is simply on behalf of Principal McCall, and I want you to take the tenor of what I say rather than the actual words. The phraseology will be altered to suit the exigencies of the case. Any alteration can be made in October when it will come up for discussion.

This concluded the business of the Council, and a hearty vote of thanks having been accorded to the President for presiding, the meeting terminated.

EXAMINATIONS IN LONDON.

At the meeting of the Board of Examiners held in London on July 7th for the Written, and on July 8th for the Oral and Practical Examinations, the following gentlemen passed their Third Examination:—

Mr. C. O. A. Anderton	Mr. G. H. Melck *
R. M. Bamford	W. B. Pershouse
S. R. Beaumont *	R. J. Stow
H. H. Curson *	R. H. Stalker
H. S. Cockburn	F. H. Stainton
E. E. Jelbart	J. F. D. Tutt *
R. H. C. Lucas	C. H. S. Townsend
A. G. E. Lalor	W. H. Wortley *

The following passed their Second Examination:

Mr. F. J. Andrews	Mr. H. C. Rockett
T. J. Bosworth	W. Shipley
F. Canilla	P. R. Turner
H. V. M. Métivier *	T. L. Wright *
W. R. McKinna *	G. S. Walker
G. E. Oxspring *	E. Wallace
R. H. Penhale *	J. H. M. White

The following passed their First Examination:—

Mr. G. Barnett *	Mr. L. Hughes
S. C. J. Bennett *	C. W. Heane *
J. C. Coleman	F. L. Haydon *
C. K. Calder	R. B. Nelder
R. Catmur *	L. E. Pritchard †
A. Carter *	C. J. Peach *
I. R. R. Coleman	S. R. Rippon *
W. A. Dickinson *	G. C. Taylor
H. J. Edwards	G. F. Watkins

Marked thus † passed with First Class Honours.

" * " Second " "

YORKSHIRE AND NORTH MIDLAND VETERINARY ASSOCIATIONS.

Attention is called in our advertising columns to a combined summer meeting on July 18th. The members and ladies will meet at the Town Hall, Sheffield, at 11.30 a.m., and an official welcome will be accorded to them by the Lord Mayor of Sheffield, Alderman S. Osborne, J.P.

After short business meetings of the respective Societies, Professor O. C. Bradley, M.D., D.Sc., M.R.C.V.S., will deliver an address on "The Present-day Veterinary Surgeon and his Successor."

Following the meeting, those present will be entertained to luncheon at the Grand Hotel, by the Presidents of the above Societies, Messrs. Joseph Abson, F.R.C.V.S., Sheffield, and F. L. Somerset, F.R.C.V.S., Chesterfield.

After luncheon, the party will be taken by motor charabancs to Buxton, where tea will be served at the Empire Hotel. *En route*, the beautiful district of the Peak will be traversed via Taddington on the outward journey and Tideswell and Bamford on the return, arriving in Sheffield in time for visitors to catch the 8.24 p.m. train for Leeds and other parts of Yorkshire.

The cost of the drive and tea will be 8/- per head, and intending visitors are requested to apply without delay to the Hon. Secretaries, Mr. J. Clarkson, Garforth, near Leeds, and Mr. J. S. Lloyd, Town Hall, Sheffield.

Swine Fever in Holland—Treatment.

In a communication to *The Meat Trades Journal*, Mr. John M. Harris, of C. and T. Harris and Co., Ltd., Wiltshire Bacon Curers' Association of Great Britain and Ireland, who has recently returned from Holland, says:—

"I visited several cattle markets and found a large number of pigs of every sort and description being exposed for sale, from the age of six weeks and upwards. In the market of Sneek there were estimated to be about 400 fat pigs and 1,000 stores. In the important town of Leeuwarden (about 30 miles from Sneek) there were computed to be 800 to 900 fat pigs and 500 stores. All these pigs were sent to these weekly markets *without any restrictions whatever*. The farmers take little notice of swine fever. When an outbreak does occur, all they have to do is to call in the veterinary surgeon appointed by the State for that district. He immediately injects a serum provided by the State into the pigs

already under the influence of the disease as well as the others on the farm."

"I last of all visited the Ryks Serum Institution at Rotterdam, which is maintained by the Dutch Government for the sole purpose of combating animal diseases. It is managed by a director (Dr. Poels) and a staff of competent veterinary surgeons, clerks, etc., and here are often kept (either at the institution or at the farm) as many as 100 horses, 50 to 100 cattle, and about 100 pigs, besides sheep, goats, fowls, etc. These animals are used for experimental purposes and the production of the various vaccines and serums, of which large and various quantities are required, as the number of inoculations runs to 400,000 to 500,000 a year. I was fortunate in finding the director (Dr. Poels) at liberty, and he was good enough to put the whole morning at my disposal. After giving me full information as to the way the serum for swine fever is produced, and showing me the animals in the various stages of the disease, as well as some that were then under operation, I addressed to him a series of questions, to which I append his answers in brief:—

1.—Is the serum treatment effective?—Out of the 4,000 injections, which were made after the pigs had the fever on them, or were in immediate contact, hardly one died.

2.—What is the cost of treatment per pig?—The serum is supplied free to the Government appointed veterinary surgeons, who charge the farmers sixpence per hog for the injection, including the serum.

3.—How long has the serum treatment been applied by the Dutch Government?—Between two and three years. Obtained the information from the Hungarian Government.

4.—How is the serum applied?—By making an injection in the neck behind the ear with a small syringe.

5.—How long does it remain effective?—If properly carried out the animals will be immune from fever for the rest of their lives.

6.—Are pigs infectious while under treatment?—Not after ten to fourteen days.

7.—What is the number of outbreaks reported in Holland?—No special reports made; but there are very few now.

8.—Do the Government make any Orders or regulations regarding swine fever?—No. Every farmer in order to prevent loss takes care to get his pigs inoculated immediately.

9.—Is it a punishable offence to remove or sell pigs while under the serum treatment?—No.

In further conversation with Dr. Poels, he informed me that a few years ago swine fever gave them great concern, but they had sent their veterinary surgeons to Hungary to inquire into the serum treatment there in vogue, the Hungarian Government having had an experience of 300,000 cases and with most beneficial results."

Commenting on the foregoing, *The M. T. J.* says:—"It is gratifying to be able to record that Sir Sydney Olivier, Permanent Secretary to the Board, has intimated that the President has given instructions for expert veterinary surgeons to proceed to Holland and Hungary in order to make personal investigations on the serum treatment, and also in regard to the procedure adopted in these countries in connection with outbreaks of swine fever."

The Vivisection of Dogs.

AMENDMENT OF THE PROHIBITION BILL.

Standing Committee A of the House of Commons, presided over by Mr. E. Wason, the Dogs (Protection) Bill was considered on Wednesday, July 2.

Dr. CHAPPLE, who moved an amendment that the Bill should apply only to inoculation experiments, said: It would differentiate between the two great classes of experiments, operation experiments and those which were not of a surgical character. If it was carried, proper surgical experiments could still go on. If a man were told that by allowing an experiment to be made upon a dog he might save his wife's life, it would be a monstrous thing to refuse, but it would not be more inhuman than the action of those who were responsible for the Bill. What vivisection had done for dogs alone was incalculable. It had stamped out hydrophobia.

Mr. A. HERBERT: Do you claim that for vivisection? Dr. CHAPPLE: Certainly.

Mr. A. HERBERT: What about the Muzzling Order?

Dr. CHAPPLE said that when the muzzling of dogs was suggested, anti-vivisectionists had raised money to oppose it and had told Mr. Long that hydrophobia was lunacy in dogs and therefore could not be dealt with in that way.

Mr. G. GREENWOOD: I entirely deny that. Some people may have done so, but not many.

Dr. CHAPPLE said that action had been so foolish that he accepted the hon. member's statement that he had had no part in it. He claimed also that through vivisection they had been able to discover how to cure many idiot children. With regard to cancer also they had been able to make discoveries through vivisection.

Sir F. BANBURY said he could not accept the amendment. He could not believe that vivisection had led to the stamping-out of hydrophobia or that through it they could make idiot children sane. If it had been the case there would have been no need for the Mental Deficiency Bill.

Mr. LYNCH said that as during 1912 out of 80,000 experiments only 500 had been upon dogs, science would not suffer if experiments upon dogs were prohibited.

Mr. ELLIS GRIFFITHS, on behalf of the Government, said he did not think it was easy to draw a distinction between the value of inoculation and of surgical experiments. He had previously suggested a compromise, and he hoped that both sides would agree that the terms of the Act of 1876 should be extended to dogs.

Mr. G. GREENWOOD said they had been asked if a man would not allow experiments to be made on dogs if that would save his wife or children. In such a case he would probably vivisection the hon. member for Stirlingshire himself (Laughter), but that would not make vivisection morally right. Sir Frederick Treves had stated that in some cases experiments upon dogs were prejudicial to medical work.

Sir H. CRAIK pointed out that Sir Frederick Treves in a letter to *The Times* had stated that he had only referred to one particular form of experiment upon dogs.

Dr. CHAPPLE said that in the same letter Sir Frederick Treves had pointed out that his statement had been taken deliberately from its context in order to misrepresent his views.

Sir JAMES LARMOR said the promoters of the Bill would do far better to direct their attention to the methods employed in the slaughter of animals.

Mr. G. GREENWOOD: We are doing so.

The amendment was carried by 12 votes to 9, and the Committee adjourned.

The Traffic in Old Horses.

GERMAN FINED £12 AT HULL.

A German horse dealer named Adolf Stones was charged before the Hull Stipendiary on Friday, 30th ult., with cruelty to three horses by walking them through the streets in Hull while in a diseased condition. The offence was committed in February of last year, when Captain Clark, of the steamer *Norwood* was summoned for bringing the animals from Aberdeen. The summons was dismissed, and a warrant was granted for the apprehension of Stones, who was the man to whom the horses were consigned by an Aberdeen dealer. Stones was apprehended at Lincoln on the 1st of May. Mr. Payne prosecuted, and Mr. Williamson defended.

Lieut.-Col. Longhurst, veterinary surgeon, described the condition of the animals. A mare, 20 years old, was suffering from a badly sprained hock, a gelding was afflicted with injury to spine and its legs were "worn out," and the third had fevered feet, the bones of which were nearly protruding.

Police Constable Bell said he saw the horses being led in from the steamer in the Princes Dock to a stable in Osborne Street, a distance of about a quarter of a mile. They were ordered to be destroyed the same day.

Defendant went into the witness box, and told the Court that he had no idea that the horses were so bad until he got them in the stable. They walked badly, but he attributed that to their having been cramped on board the *Norwood* for two nights and one day. Asked why he sold up and cleared out of the country when the warrant was issued, defendant said he was frightened by people telling him he would have to "do time."

Cross-examined by Mr. Payne, defendant said he gave £32 for the three horses. He was going to take them to his stable and dress their legs and make them a good bed for two or three nights. After this treatment they would look better and younger. Then he was going to send them to Rotterdam to be slaughtered.

Slaughtered for sausages?—Yes.

The Stipendiary: He says "Yes"; apparently he knew all about it.

Mr. Payne: What do the Rotterdam people pay for them?—We have got up to £15 and £20.

Mr. Payne: According to your story it would pay to breed horses to send abroad for sausages?

The Stipendiary: These men will fight very hard to get the horses exported alive, instead of having to send them to the "knackers" yard.

Mr. Payne: Should you not carefully examine a horse before bringing it from the ship?—I always do. On this occasion there was no chance on board, and there was room on the quay.

Why did you run away?—I was frightened by other people. I have been fined a few times, and they told me I should go to prison.

But you say you are an innocent man?—Yes.

The Stipendiary: You had better go back to Germany if you think this is a dreadful country where innocent people are sent to prison. Continuing, His Worship said the past offences were not serious.

Sergeant Pearcey, inspector of old horses under the Hull City Corporation, said he had known the prisoner for nine years, and had had a good deal of trouble with him. On two occasions, when horses had had to be shot, he had during the absence of the inspectors taken them away to be resold. This happened two years ago.

The Stipendiary said this case, so far as the condition of the animals was concerned, was the worst he had

ever heard. He remembered making the order for their destruction, and he might say that he never saw such horses, and he hoped he never would see such horses again. Anybody who saw them walk a yard must have been convinced that they were not fit to travel. He imposed fines amounting to £12, with the alternative of three months' imprisonment, and he refused to allow the prisoner any time to pay.—*Hull News*.

DIRECTOR-GENERAL A.V.S.

We hear that the Army Council have decided that the appointment of Director-General, Army Veterinary Service, will in future be four years, as in the case of other staff appointments. Up to the present, the appointment has been for three years, but the Army Council have had the power to specially extend it for a further period not exceeding two years.

The present holder of the post is Maj-General R. Pringle, C.B., D.S.O., A.V.S., who was appointed on Oct., 1910.

The Directorate is one of five in the Department of the Quartermaster-General to the Forces. Its entire War Office staff only includes half-a-dozen individuals. These are the Director-General, an Assistant Director-General, and four ex-military clerks. Their combined salaries amount to £2,395, of which sum the Director-General receives £1,200, and the Assistant Director-General £700.—*Military Mail*.

Personal.

GOLLEDGE—CULPIN.—On June 28th, at St. Paul's Church, Camden Square, by the Vicar, the Rev. G. Filey, assisted by the Rev. W. B. Tweddell, Mr. Hedley C. D. Golledge, M.R.C.V.S., Board of Agriculture, Ashford, Kent, son of Capt. and Mrs. C. Hedworth Golledge, Kingston House, Sherborne, Dorset, to Edith K. Culpin, only child of Mr. and Mrs. W. H. Culpin, 64 Camden Square, London, N.W.

Sir STEWART STOCKMAN has recently been incapacitated by a serious illness, from which he has not yet completely recovered. He was away from home when the nature of the malady—typhoid fever—first became apparent; and this necessitated a stay for some weeks in a hospital in the country. Happily he is now recovering, has left the hospital, and may fairly be called convalescent. All veterinary surgeons will join in wishing him a speedy restoration to complete health.

The many friends of Mr. T. Salusbury Price will be glad to hear that he is making good progress towards recovery from the severe accident which befell him last month.

OBITUARY.

JONATHAN RINGROSE, M.R.C.V.S., Weaverthorpe, Yorks.
Graduated, Edin: April, 1864.

Mr. Ringrose died from diabetes mellitus, embolism of pulmonary artery, and syncope, on July 2nd. Aged 69 years.

CORRESPONDENCE.

INSPECTORS' FEES.

Sir,

The sentiments expressed by Mr. H. Gray will be endorsed by all practitioners who place a proper value on their time and services. It is not the public who arrange a scale of fees in any district, but it is the practitioners who really appraise the value of professional services. Public bodies no doubt desire to get work done as cheaply as possible, but the remedy for insufficient remuneration lies in the hands of the veterinary surgeons themselves. Evidently with all our boasted advancement, we are not progressing so far as increased pay is concerned. Why are fees cut down to a starvation scale? Simply because men can be found who place very little value on their time and services, and by working for wretched fees they manage to exist somehow. But there are cases in which cheap work is done in order to attract clients from another practitioner; those who practise this plan do so for the sake of greed, knowing full well that the skill which they possess cannot accomplish the desired end.

But things have indeed come to a pretty pass when, if we sue either a public body or a private individual for proper remuneration, we may find a qualified man ready to testify that half the amount we are claiming would be just and proper.

If some of our members of Council, endowed with forensic abilities, would get a clause inserted in the new Bill to deal with cases of the above kind, we might then get some value for the registration fee.

I have experience of one instance in which a V.S., in order to get appointed to a certain horse-show, offered his services *gratis*, although I was for years getting £3 3s for doing the work!

No doubt cases of this kind are of too commercial a nature to merit deep consideration, and those who are never tired of describing the evils of quacks, can close their eyes to the mean contemptible acts of individuals licensed to add the mystic letters to their names.

We hear a lot about professional etiquette at meetings of veterinary societies and at the post-prandial orations that usually follow, but in actual practice it is generally regarded as "a counsel of perfection," and is "more honoured in the breach than in the observance."—Yours, etc.,
E. WALLIS HOARE.

SOUTH DURHAM AND NORTH YORKSHIRE V.M.A. A CORRECTION.

Dear Sir,

In the report of meeting last week on p. 10, in the scale of suggested new fees by the Durham County Council, fees for attendance at markets, sales, etc., should read:—

For examination of a single animal	...	10	6
.. further animals 1/- per head.	...		
up to a maximum of	...	£1	10 0

JAS. H. TAYLOR, Hon Sec.

Original articles and reports should be written on one side of the paper only and authenticated by the names and addresses of writers, not necessarily for publication.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1306.

JULY 19, 1913

Vol. XXVI.

THE "NATIONAL" MEETINGS.

The "National" meetings will commence in London ten days hence. Time, place, and programme have already been advertised; and all will agree upon the interest and variety of the subjects for discussion: the chief thing necessary for a successful re-union is a good attendance.

One or two other things are essential to ensure a smooth working. Those who intend to be present at the annual banquet should not fail to give notice of their intention in good time. And those who require information regarding hotels or other particulars from the Hon. Secretary to the Provisional Committee should communicate with him at once—he cannot be expected to answer many letters arriving at the last moment. By remembering these points, members can save endless trouble to the organisers.

THE INTERNATIONAL CONGRESS.

Those attending the "National" meetings may do good service by endeavouring to interest others in next year's great International Congress. The Congress Fund is making steady progress, but still needs support from all of us. In addition to the sum already subscribed and promised, about £400 is now required to bring the total to the absolute minimum necessary for success; but we ought to go well beyond the minimum. From the first it has seemed probable that the Congress might be a record one—its history since its inception has been one of steady numerical increase. And, as a matter of fact, information is now to hand from abroad which goes to indicate that the Congress will again break its own record as regards attendance. Obviously, the expense will rise with the attendance.

Those members who have already supported the Congress only amount to a very small proportion of the profession. The majority of members have not yet subscribed at all: and this fact, while it does not speak very well for our collective public spirit so far, shows clearly that all the money required can easily be raised if we choose. So large a proportion of it has already been raised by so few men that all that is necessary now is a comparatively small amount of support from the rest. It remains to men who have already subscribed to endeavour to induce others to do likewise.

THE ASSOCIATION OF VETERINARY INSPECTORS.

As announced on another page, this young and energetic Association is to hold a meeting at "The Holborn" on Monday 28th. It already numbers over 200 members and its membership is steadily increasing. A note in our correspondence page shows that its existence is justified.

DISLOCATION (?) OF THE NECK.

The patient, a half-bred Nellore heifer in good condition was brought into the Veterinary Hospital at Vizianagram in this Presidency, on the day I happened to be inspecting it.

History. The owner stated five weeks previously he found the heifer in the morning, with what he called a swelling on the right side of her neck, she having been left tied up during the night in a shed with other animals, in a perfectly sound condition. He described the swelling as being slightly painful and about the size of the palm of one's hand. An uneducated native of this country, however, is so inexact and unobservant, that it is difficult to place any reliance on his description.

As is done in most diseases of animals in this country, the owner fired the place, but, as stated by him, although he repeated this twice during the five weeks, it continued to enlarge and the head became more turned to the left.

Symptoms. In reality there was no swelling, except that which had been caused by the repeated firing, and the cervical vertebrae could be easily traced under the skin along the greater curvature, as seen in photo No. 1.

The funicular portion of the ligamentum nuchae was considerably shortened, hard, and tense, and displaced well to the left of the cervical vertebrae. It formed the upper margin of the deep depression in the middle of the neck shown in photo No. 2, and at first sight looked as if it were undeveloped and had been the primary cause of the curvature.

Diagnosis. Owing to the thickening caused by the repeated firing, and the length of time which had elapsed since the original accident, it was not possible to make out any displacement of the bones, but the only explanation that occurs to me is that on the night before the swelling was first noticed, the heifer had an accident, and dislocated some of the bones of her neck, giving the head a kink to one side.

The continued steady traction of the ligamentum nuchae whose action would now be exerted on one side only, would do the rest, and, as it became shorter, gradually pull the head round into the position seen in photo No. 1. To show how firmly fixed the head was in that position it may be noted that it was not possible to straighten the neck more than is being done by the attendant in photo No. 2.

Remarks. In England one would at once advise the owner to fatten and sell, for the heifer could feed well enough to make this possible. In this country, however, Hindus look upon the taking

of life with repulsion and, in fact, it is opposed to their creed. For this reason, and for the sake of the popularity of the hospital, one dared not attempt the heroic treatment of trying to reduce the curvature, for the most likely result of that appeared to be the breaking of the animal's neck.

I have to thank the assistant in charge of the hospital, Mr. Aiyasawmi Pillai for obtaining the photos.

Since writing the above I have come across a cutting from *The West Kirby News and Advertiser* in *The Veterinary Record* of 15th March, 1913, in which what seems to have been a similar case in a filly is described as having been successfully treated by Mr. Percival Carter. I should be very interested to hear his exact method of treatment.

F. WARE, I.C.V.D.,

Madras.

"MILK FEVER": SUGGESTION FOR PREVENTION.

By W. E. BLACKWELL, M.R.C.V.S., Towcester.

During the past five years I have seen many cases of this disease, and certain facts have impressed me so much that I record them in order to learn whether others have observed them, and noted their significance. What I want to say is with regard to prevention, which, as everybody knows, is better than cure, although it certainly does not bring much into the coffers of country practitioners.

Every case I attend I ask this question: "I suppose when this cow calved you milked her out?" and the answer I get is always Yes! When a cow is affected, I always get such a history of her case. The farmer follows the custom of his ancestors, and also the practice of the present time, and empties the udder, instead of allowing the calf to take a little out at a time, as would be the case in the natural way. The result is that the cow goes down with Milk Fever. Not, of course, in every case, or even in the majority of cases, but, in my experience, this procedure is always the antecedent in cows which develop the symptoms of the disease.

And what is the treatment which usually brings about such "magical" recoveries in the great majority of cases? It is this: that either by air, antiseptic fluid, or both, the udder is distended until it assumes the state it was in, before the cow was first milked out.

Whether the cause of Milk Fever is a toxin generated by anaerobic bacilli within the gland I do not know, but pressure on the veins to prevent further absorption of whatever the cause may be, seems to be the thing required—assuming that the cause enters the circulatory system in this way.

I have had two cases within the last few days, and both cows had been calved between 30 and 40 hours when I saw them. The first one was left absolutely alone according to my advice, the calf alone drawing the udder. This cow had a slight quivering of the muscles of the hind quarters, but she rapidly regained herself without any treatment whatever.

The second one had been milked four times, in addition to what the calf had got by sucking. Before the fourth milking she was staggering a little, but one hour afterwards she was much worse, and had some difficulty in maintaining the standing position. In order to test my theory I explained to the owner that he should leave her alone, put a muzzle on the calf and thus allow the udder to get distended again, and to keep her under close observation. Eighteen hours afterwards she was chewing the cud, and quite normal, having rapidly improved after my first visit.

I do not say it is right to do nothing at all in such cases, but it is better not to inject anything into the udder if one can bring about the same results by avoiding it. A client of mine who carries out this practice has not had one case since, although he has a herd of dairy cows numbering about 30. I myself shall lose considerably if I get only an odd case of Milk Fever now and again, but I am reporting this to the profession and not to the agricultural papers, although it may probably find its way there, and I shall never mourn because of that. Obviously this practice will not prevent those cases which sometimes occur three months or so after calving, or those cows from falling which are barren at the time of the attack. My suggestions then amount to this:—

Do not milk the cow for 48 hours after calving, but allow the calf to suck in the natural way. Then milk the cow night and morning and allow the calf to suck her for a week or 10 days, although that does not matter much if the 48 hours after calving are devoted to this method.

KERATOMA.

The accompanying photograph represents a good specimen of keratoma or horn-tumour of the horse's foot, showing the tumour in the lower part of the horny foot with corresponding gap in the pedal bone.

These growths are not very commonly met with. They are caused by pressure, and are found both in the front and hind feet, more particularly in the heavy breeds of horses. They are generally met with at the toes, but also form on the sides (chiefly in the front feet) where the clips of shoes are situated.

The foot shown in the photograph was the near fore of a heavy van gelding. The foot was first treated for canker of the sole and frog, and did well. Severe lameness followed with suppurative of the toe, and as the lameness did not improve and disease of the pedal bone was suspected, the horse was cast and the wall stripped over the diseased part.

The progress of the case for several months afterwards was somewhat slow, but the horse gradually improved from its lameness, and when once the wall had grown down it was likely to regain soundness sufficient for walking work. Unfortunately it was kicked by another horse, and had to be destroyed for open hock joint.

R. EAGLESHAM, M.R.C.V.S.

Paddington.

A PORTABLE BOX FOR TUBERCULOSIS INSPECTORS.

When the Tuberculosis Order came into being in May last, the Berks Inspectors were supplied with large, thick, heavy widemouthed jars with a capacity of about 40 oz.—somewhat resembling the ordinary stock surgery bottles—for the purpose of taking samples of milk from cows notified under the Order. These vessels were impracticable. Besides being cumbersome and difficult to take about in a car or trap without being broken, they were unsuitable for sterilisation, and when four had to be taken out to a case it became a matter requiring some ingenuity to pack them safely. The inconvenience and annoyance caused by one experience of these prompted me to devise the box shown in the illustration.

I called on Messrs. Baird and Tallock, 14, Cross Street, Hatton Garden, and gave them my ideas and suggestions, and they have succeeded in making quite a handy, portable little box, measuring 11 in. x 9 in. x 9 in., which is strong enough to take any ordinary rough usage. The lid is secured by a strong lock and hooks, and has a substantial leather strap provided for use as a handle. Inside, the box is divided into six partitions, which together with the lid are well padded with thick felt. The four larger spaces are for 10 oz. wide-mouthed stoppered jars or bottles for holding the samples of milk—quite large enough, I think, for all requirements; the two smaller divisions for smaller stoppered bottles—one to hold liquid soap for washing the udders, and the other for an antiseptic for sterilising the teats and udders after washing. I have found the box quite satisfactory and very useful, easy to carry about and stow away in trap or car, and can recommend it to my brother inspectors.

GEO. EDWD. KING.

The Vineyard, Abingdon.

ABSTRACTS FROM FOREIGN JOURNALS.

FILARIA PAPILLOSA IN MONGOLIAN HORSES.

Hellmuth reports (*Zeitschr. f. Vet.*) that he has repeatedly observed the appearance of *Filaria papillosa* in the eyes of Mongolian ponies in Eastern Asia. The natives of the region say that the worm generally appears after the rainy season, and often disappears spontaneously, but in most cases leads to destruction of the eye. Hellmuth describes the parasite as a round filamentous worm pointed at the end, about 1 3/5th inch long, and as thick as a knitting needle, which executes very lively twisting movements after the manner of an eel in the anterior chamber of the eye, and prejudices the vision of the horse by its turbid excretion. In one case, Hellmuth undertook the operative removal of the parasite; and the patient, an eight-year-old brown pony gelding, bore the operation well and made a complete recovery.—(*Berliner Tier. Woch.*)

ACCIDENTAL DIVISION OF THE TENDONS OF THE HIND LIMB IN THE OX.

P. Herbert records (*Journal de Méd. Vét. et de Zootechnie*) the case of a nine-year-old ox which, while harnessed to a mowing machine, had the cannon region of the left hind limb caught between two of the teeth of the machine, with the result that the tendons were completely severed.

The ox was immediately unharnessed, and was then only able to move with great difficulty. The foot of the injured limb was mobile from behind forwards; and weight was borne only upon the posterior part of the pastern, the foot being carried strongly forwards.

The animal was Herbert's own property, and he decided to attempt treatment. He lodged the ox in a neighbouring stable; and, by a preliminary dressing, he arrested hæmorrhage and disinfected the wound. Then, for some days, he carried out continuous irrigation of the wound with cold water, to which a little lysol was added. The ox got up of his own accord. Several times every day, remained standing for from fifteen to twenty minutes, and then lay down again—sometimes upon one side, and sometimes upon the other.

When the irrigations were discontinued, a dressing with iodoform was applied daily.

A month after the accident, the wound was cicatrised; and, though the lameness was still as intense as at the beginning, recovery was assured. The connective tissue which had formed between the ends of the tendons hardened imperceptibly, contracted, and brought the divided ends together, so that at the end of three months the ox resumed his daily work. The lameness had completely disappeared, and the foot had resumed its normal position.

This observation, which agrees with others previously made by the author, proves clearly that

recovery from accidents of this nature may be obtained without suturing the cut ends of the tendons.—(*Annales de Méd. Vét.*)

W. R. C.

[In considering the bearing of this case upon similar accidents in horse practice, it is perhaps advisable to remember that the ox only performs very slow work.—*Transl.*]

SOUTHERN COUNTIES VETERINARY SOCIETY.

The summer meeting was held on Thursday the 26th June at the George Hotel, Portsmouth, when the new President, Mr. G. H. Livesey, of Hove, took the chair and the other members who signed the attendance book included Messrs. A. H. Archer (Southsea), J. T. Angwin (Arundel), E. Whitley Baker (Wimborne), W. A. Della Gana (Southampton), W. W. Henderson (Haslemere), C. Pack (Lymington), W. E. Petty (Southsea), and J. Alex Todd (Worthing), Hon. Sec.

On the proposition of Mr. E. Whitley Baker, seconded by Mr. J. T. Angwin the minutes of the last meeting as published in *The Veterinary Record* were taken as read and confirmed.

Apologies and letters of regret at inability to attend were announced from Prof. Hobday, Messrs. R. Burt, W. Burt, Junr., W. A. Collins, W. Coveney, J. B. Dier, Henry Gray, C. W. Howard, H. H. Jeffries, J. B. Martin, A. Maynard, W. F. Maynard, J. C. Munby, S. H. Slocock, C. H. Spurgeon, H. Smith, P. J. Simpson, Theo. C. Toope, R. A. Thrall, A. Whicher, and F. T. Walder.

It transpired that the absence of Mr. Martin was due to an acute attack of influenza, and Mr. E. Whitley Baker suggested that as Mr. Martin was one of the oldest members as well and one of the founders of the Society and its original Secretary, they should send him a wire conveying their good wishes and their hope that he might have a speedy and complete restoration to health.

Mr. Angwin seconded, and the President having cordially endorsed the suggestion, a telegram was despatched to Mr. Martin in the following terms: President and Members of Southern Counties Veterinary Society regret cause of your absence, send you good wishes and heartily wish you a speedy and long continued restoration to good health.

It was also resolved on the proposition of Mr. Whitley Baker, seconded by the President, that the Hon. Sec. should send a letter to Mr. A. Maynard, of Bournemouth, in similar terms.

The Hon. Sec. reported the circumstances which had led to the venue of the meeting having been altered from Bournemouth to Portsmouth, and mentioned that Mr. Archer had written that in the event of their meeting at Portsmouth and ladies being invited, it would have given his partner and himself much pleasure to have entertained the members and their friends to tea on the South Parade Pier, where a room for the meeting could also have been obtained. Mr. Todd added that he consulted the Executive Committee who were of opinion that owing to the short notice and other reasons it was inadvisable to take advantage of the offer on the present occasion and he had accordingly written to Mr. Archer to that effect, at the same time thanking him on behalf of the Society for the very kind invitation.

The President: I think the least we can do is to endorse that by passing a special vote of thanks to Mr. Archer to-day and informing him that it was on

the advice of the Executive Committee that the Secretary acted as he did, and that this meeting confirms his action.

Mr. Angwin made a proposition to that effect, Mr. Henderson seconded and the resolution was unanimously agreed to.

Mr. ARCHER on being informed of the resolution on his arrival at the meeting a few minutes later, briefly acknowledged the compliment, adding that they would have been very pleased to have entertained the Society.

The Hon. Sec. submitted a letter from Mr. Theo. C. Toope with reference to the question of the fees paid by Insurance Companies and also that of the fees and allowances made to Veterinary Inspectors. In connection with the latter matter, Mr. Toope wrote that he was desirous that some attempt should be made to better organise their members for acting in concert, and he made various suggestions for achieving this result, one of which was to call meetings of the Veterinary Inspectors on the same days as the general meetings of the Society, at which these matters could be discussed, and then to appoint four or five members as a standing Committee to deal with all matters affecting veterinary inspectors specially.

Mr. E. WHITLEY BAKER: I think we might ask the Veterinary Inspectors in our district to meet just prior to our next meeting and then Mr. Toope's suggestion can be laid before them. I move accordingly.

Mr. PACK seconded.

Mr. ANGWIN: Will any veterinary inspector who is not a member of this Society be able to attend?

The President: Undoubtedly.

The proposition was then put and carried.

The President asked the members to rise while he made a brief reference to a very sad matter. Since their last meeting, one of their oldest and most esteemed members in the person of Mr. R. Roberts, of Tunbridge Wells, had passed away. Unfortunately his death occurred without Mr. Todd becoming aware of the fact until some days afterwards, and he personally knew nothing of it until he read the report in *The Record* on the following Saturday. The consequence was they were not officially represented at the funeral and no wreath was sent, either which he was sure they all much regretted. Mr. Roberts was one of their most esteemed members. Not only was he an excellent veterinary surgeon and an old practitioner who had kept himself thoroughly up to date, but he was a first-class man all round, and whom to know was to feel he was a friend. Their Society and the whole of the veterinary profession had lost a very great deal by his death, and particularly would they miss his genial presence at their meetings. He knew as a fact that he took the very greatest interest in their Society, and that he had a feeling of great personal friendliness with every member. They could only trust that his practice would continue to flourish in the hands of his son Mr. Charles Roberts, who was also one of their members. He was extremely sorry they were not able to be represented at the funeral, but they could at least ask their Secretary to write a letter now to the family expressing their sincere regret at his loss and their condolence and sympathy with them in the sad bereavement they had sustained.

Mr. DELLA GANA seconded, and the proposal was at once agreed to in silence.

The President added that he thought it might be as well if the Secretary sent a transcript of what had just taken place; Mr. Roberts might then see that it was not simply a formal resolution, but that it was really intended to represent their feelings in the matter.

The Hon. Sec.: I shall see that that is done, Mr. President. I may say that I knew nothing of his death until I saw the report of the funeral in the papers, but I immediately wrote to Mr. C. Roberts explaining why no wreath was sent, and why we were not represented

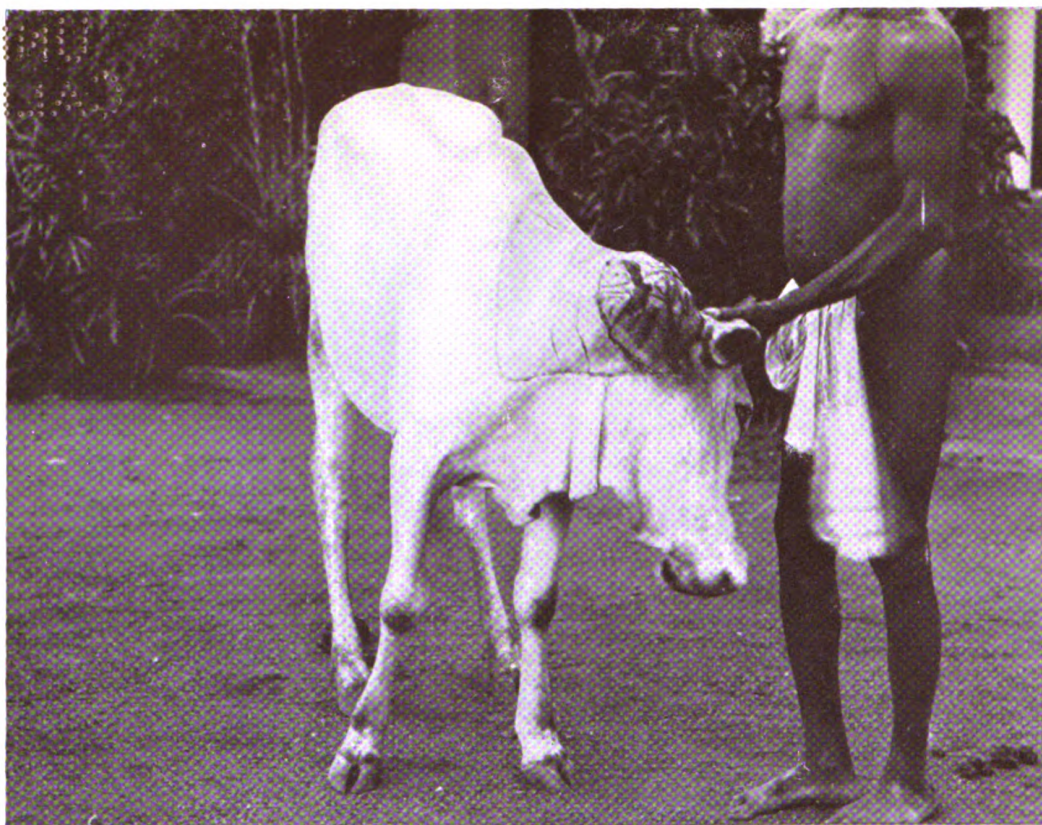

KERATOMA.

DISLOCATION (?) OF CERVICAL VERTEBRÆ IN A NELLORE HEIFER.
Note by Mr. F. WARE, M.R.C.V.S., Indian Civil Vety. Dept.

at the funeral, and also my only regret that I could not attend; and he sent me a very nice and appreciative letter in reply.

New Members.—Mr. W. E. PETTY, of Southsea, who had been nominated by Mr. Archer, and seconded by Mr. P. J. Simpson, at the last meeting, was formally elected a member, and was cordially welcomed by the President.

Capt. OLIVER, of the Army Veterinary Corps, recently stationed in Egypt, and now residing in England on leave, was nominated by Mr. Angwin for election as a member at the next meeting; this was seconded by Mr. Archer.

On the proposition of Mr. Angwin, seconded by Mr. DellaGana, it was decided to hold the next meeting at Brighton on the last Thursday in September.

The PRESIDENT intimated that he would have much pleasure in entertaining them either to lunch or tea whichever they preferred. He hoped that if they made it lunch, they would turn up in good numbers and let them have a really big meeting. (Hear, hear).

PRESIDENTIAL ADDRESS.

Mr. LIVESEY explained that he had not had time to prepare a proper address. All he had done had been to string together a few rough notes. If they wished it he would do his best with these, or he would try to get them something better for the next meeting.

Mr. E. WHITLEY BAKER: I think we should prefer to hear what you have to give us to-day, Mr. President. (Hear, hear).

The PRESIDENT: Well, gentlemen, I must first of all thank you for having elected me to the chair. It gives me particular gratification to be President of this Society because it is a Society in which I have always taken a very great interest. It certainly has some attributes which appeal to me that other Societies have not, and when one is a member of a Society which one likes particularly, there is nothing more gratifying than to be eventually called upon to take the chair. In a presidential address it is usual, I believe, to review matters that are before the profession, and presidential addresses are also, I believe, as a rule extremely dry. Still, these things have to be given, and if my views are not exactly the same as those of some of the other members, it may perhaps add a little piquancy to what I have to say.

Undoubtedly the matter that occupies our attention most to-day is the Bill that is now before Parliament. It is in my opinion the most important question that is before the profession at the present time, and it is a matter also I think that deserves our warmest support and our most earnest consideration. The Bill is necessary I take it for many reasons. It is necessary in order that the College may avoid bankruptcy in the first place, and secondly it is necessary in order that we may re-establish ourselves on a sound financial basis. There has been a good deal of controversy as to what the levy on the members should be. We might make ourselves financially sound on a 10/6 basis. That at any rate is the opinion held by a great many of our members, and I must say that I am inclined to agree with them, but I would ungrudgingly give my guinea, and I think practically the whole of the profession would do the same. I think the half-guinea is absolutely necessary, but I also think the guinea would be very much better. A guinea subscription would bring in a surplus, and while on this aspect of the matter I might observe that it seems to be exercising the minds of a great many of us as to what should be done with that surplus. Letters have been written in *The Record* on the subject, and it has also been discussed when members have met together at the meetings of the various Societies. A large number seem to be under the impression that the first necessity after paying our expenses is to set up a fine library and museum, but I am not one of those who

agree with that. A library and museum do not seem to me so important as to have large invested funds and a good cash balance at the bank. This Society was one of the first to urge, and urge strongly upon the Council, the necessity of fighting quackery, horse dentists and dog doctors and those sort of people. To that end we made a special effort to get our own representative on the Council in the person of Mr. Walter Burt, and later he was joined there by Mr. Richard Roberts. Those two representatives on the Council worked hard in our interests, and they have both done their best to let the Council and the Registration Committee see how urgent is the necessity for putting down, as far as possible, quackery, and the illicit practising by those who profess to be veterinary surgeons while calling themselves by some other title which may or may not be an infringement of the Veterinary Surgeons Act. To carry out this work successfully, however, money is urgently required. The members of our Parliamentary Committee are almost crippled in their work by the lack of funds. It seems to me that more money to help the legal and Parliamentary work of the Council is our immediate necessity, and our funds should be used in this direction before we spend them on the luxury of a fine library and museum. Our first duty is to establish the profession on a sound basis and so guard it that it cannot be assailed. When we have done that it will then be time enough to gratify our pride by having new premises fully equipped with a library and museum worthy of the profession. Next year an International Veterinary Congress is to be held in London, and I trust it will be a great success and do us good by bringing us and the importance of our work prominently before the eyes of the public. My only regret is that the Congress is to be held next year and not some years hence, for it seems to me that the time is hardly yet ripe for such an event. For is not our College rapidly running into bankruptcy, and while we are arguing among ourselves and in the columns of *The Record* as to whether we shall pay 21/- or 10/6, or even nothing a year to support our tottering governing body, were are being asked at the same time to find £3000 to entertain a lot of foreign gentlemen who may well go home after their meeting laughing at the way we manage to look after ourselves and our interests. Charity we are told, begins at home. However, now that all the details of the Congress have been arranged it only remains for us to see that it is carried through with energy, tact, and thoroughness. To turn to another matter, the profession is to be congratulated, I think, on the position of importance it is called upon to take under the Tuberculosis Order and on the skilled work it has to perform, and I sincerely hope the Milk and Dairies Bill will soon become law and bring more grist to our mill and further enhance our reputation as a profession. Although so poor financially, the profession has I think prospered in many other ways. We are, for instance, now established and recognised as a profession, and it is no longer an indignity to be a veterinary surgeon. I say this advisedly, because I can remember many years ago, when I thought I would like to become a veterinary surgeon, some of my friends in the north pooh-poohed the idea, and held up before my eyes the indignities that were generally put upon veterinary surgeons. But those days have now passed away, and veterinary surgeons are able to take up the position which they ought to take. This I think is largely due to the position that has been taken up by the Army Veterinary Service, and here again I had a personal experience which might be worth relating. I remember that when I mentioned to some other people in the north that I was going to study for a veterinary surgeon, they remarked "You are not going into ordinary practice surely: if you go into it at all you will go into the Army." I replied that I might or I might not, but I thought I would prefer private

practice, and they told me then that the Army Veterinary Service was the only place where I should get my proper status. I only mention this as an illustration of the position the veterinary profession then held in the eyes of the public. Those days have, however, now changed for the better, and the veterinary surgeon has taken his proper status in Society. He meets other professional men on an equality and very often as their superior. This change is due in a great measure also to our hanging together and being more friendly among ourselves; and this friendliness has been greatly fostered and increased through the agency of societies such as ours. This is one reason why it is such a pleasure to me to be a member and why it gives me particular pleasure to have the honour of being President of this Society. I have never yet known of a single member being present at any of our meetings and being unwelcome. All are friendly with each other and our meetings are pleasant re-unions. I sincerely hope our Society may long continue to hold the reputation it has gained throughout the country for good fellowship. (Applause).

Impromptu discussions on subjects drawn by ballot occupied the greater part of the remainder of the sitting.

"JOHNE'S DISEASE."

Mr. ANGWIN, whose name was drawn, observed that he thought they must almost be getting tired of hearing him on this subject, after the two papers he had given them on it. He did not propose to detain them very long that afternoon however. He was still studying the matter, and he might tell them that he had got some beautiful specimens from which he had been trying to make some micro-photographs, because he had promised their hon. sec. a paper at the end of the year on the daily use of the microscope in practice. He had already got about twenty-five slides prepared, and he hoped to be able to show from thirty to thirty-five on the screen, and to give them material for a really good discussion later on. Personally he did not think this disease had abated in the slightest, at all events in that neighbourhood. He had two cases quite recently and he wrote at once to Mr. Twort for a supply of his vaccine, which he used, and he took the temperature every two hours for eighteen hours. Neither of the cows had reacted to tuberculin, and he was perfectly certain they were not tuberculous. He must admit the vaccine he used on this occasion was rather cloudy, but at all events he did not have any results. When tuberculin first came out it was very much over-rated and it took several years before the public and the profession found that it was simply a diagnostic agent. There was, however, no more satisfactory diagnostic agent used in his opinion than tuberculin when it was properly done and the temperatures properly taken, and they must not be too hurried in coming to a conclusion about this vaccine. If they waited a bit and used it carefully he thought they might discover either that it was an ordinary diagnostic agent, or possibly it might be found to be curative.

Mr. DELLA GANA: What quantity did you use?

Mr. ANGWIN: Two drachms.

Mr. PETTY, who was called upon to continue the discussion, remarked that this was a subject he knew very little about. As far as Twort's vaccine was concerned, he had had no experience of it at all, but as far as Johne's disease was concerned, he believed it was claimed to have been seen in dogs on several occasions as well as in cattle. He did not see any reason why they should not be able to prepare a similar agent to tuberculin as a test for it eventually. The bacteria themselves were extremely alike, and they were probably of the same family; Tuberculosis often took on an intestinal form, they were both tissue parasites, and they

were also similar in other respects. The diagnostic power of tuberculin was a matter that was very much under discussion. Whether it was all that it was reputed to be or not he could not say, but he thought it ought to be put under State management and standardised.

Mr. HENDERSON, like Mr. Petty, was obliged to admit that he had had very little experience of this disease, but it was a subject that had been occupying his attention for some time. He had one case of a pig which made him think it was possibly this disease. The symptoms were analogous to those they found in the cow. The only thing he found that acted with any success in abating the diarrhoea was liquid paraffin, or petrol. The curative effects of this, however, were only temporary, and the discharges came on again as bad as ever after a time.

Mr. ARCHER remarked that this Johne's Disease was one of which he had seen a good deal in former days, but not much lately. It used to be called intestinal tuberculosis or consumption, but for quite a number of years now they had recognised it as being an entirely different disease. Personally he did not think the parasite had any near connection with those of tuberculosis. Although they gave symptoms which might be mistaken for each other, the general effect upon the system was quite different. Neither did they yield to the same treatment, because in many cases where they got tuberculosis in the early stages they could check it to some extent by treatment, but his experience of Johne's Disease had been that it was absolutely impossible to do any good. The best thing he had ever tried had been powdered cinnamon but he did not suggest this as a specific. Unless very great care was exercised with Twort's vaccine he was afraid the results would be disappointing. He had the privilege of a personal interview with Mr. John Burns about seven weeks ago, and this tuberculin question was one of the things he tried to impress on him very strongly. He pointed out that there were a great many individuals who injected their cows periodically and thus rendered them more or less immune to the action of tuberculin, although the animals might be tuberculous, and that the state of things would nullify to a considerable extent the objects of his Bill. Mr. Burns replied, "Yes, I see that is a serious matter, but is there any way in which we can check the sale of tuberculin?" He replied that he was afraid there was not by the British Government, because anyone could get it from abroad just the same as in England. Mr. Burns then asked if there was anything he could suggest that would enable them to check the sale and use of tuberculin, and he replied that he thought something might be done by making it illegal for anyone but a qualified man to use it. In other words treat it as a dangerous drug or poison. That was the only way in which they could check the use of it. He did not say it would stop it altogether, but it would certainly check the indiscriminate use of it to a very considerable extent. Mr. Burns admitted that that seemed a feasible and practical way of doing it. He (Mr. Archer) had also been in communication with Mr. Runciman on the same subject, and he was assured that it was under consideration; and he trusted that this consideration might be the means of leading to something being done.

Mr. DELLA GANA remarked that he had very little to say on this subject except that he thought the disease was very much akin to tuberculosis, and that he hoped Mr. Twort would succeed in producing some form of serum which would be efficacious in diagnosing, if not in curing the disease.

Mr. PACK said that there did not appear to be any very definite knowledge as to what this disease really was. That it was a bacteria infection of the intestines there was not the slightest doubt, and it was also a most

insidious disease, but beyond that they knew very little. As far as treatment was concerned he had never had any good results. It was a mistake to suppose the scouring would never stop because it would stop for months, but one always felt on tender hooks as to when it was going to start again, and the chances were that sooner or later it would, at all events his cases had always ended in the animals getting so emaciated that they either died or had to be poleaxed. Lately he had had the disease cropping up in single cases. In one case in particular he got a decided re-action to the tuberculin test and put her down as tuberculous. A sample of the milk was sent up but the report came back "No tuberculous bacilli." In the meantime the animal had started scouring, and as it was becoming very emaciated he reported her as tuberculous and had her slaughtered, when he found plenty of evidence of Johne's disease but none whatever of tubercle.

Mr. E. WHITLEY BAKER on being appealed to continue the discussion was afraid he could not add anything to what they had already heard. The most interesting part of the discussion to his mind had been what they had just heard from Mr. Pack. It seemed to him that if they were going to get a reaction to tuberculin in cases of Johne's Disease they would be in a fix later on.

THE TUBERCULOSIS ORDER OF 1913 AND ITS EFFECT ON THE VETERINARY PROFESSION.

Mr. ARCHER, who was called upon to open, observed that he believed they would find this Order and the Milk and Dairies Bill were going to have a very important effect upon their profession generally. He understood that the veterinary inspectors, of whom he did not happen to be one, were forming an association with a view to fixing the fees to be charged for the inspection of animals under these two Orders, and that they were excluding the unqualified practitioner from their ranks. He quite approved of that, but seeing that the Bill proposed to give the unqualified man the same position as the ordinary practitioner, it seems a little inconsistent to exclude them from the new Association, because it would give the unqualified men an opportunity of charging what they liked. What was going to happen he was afraid was this—the general practitioner would find that his practice would be encroached upon by the Inspector, whoever he might be, because the owner, when he had an animal ill from any cause, would for his own protection report it to the Authority. The latter would send an inspector down to see it, and it would at once pass out of the general practitioner's hands into official hands, and in some cases it might happen that when an inspector went to see an animal reported as being a suspected case, he would suggest treating it for a little while to make sure. This was what had already happened in his experience.

Mr. E. WHITLEY BAKER remarked with reference to the appointment of unqualified men as inspectors, that he failed to see how members of their profession could recognise them as members of the Inspectors' Association. How they were going to deal with this aspect of the matter he did not know, but it seemed to him that the only course they could with dignity take would be to do what Mr. Archer had done with regard to the sale of tuberculin—and approach some Parliamentary Authority. The only other remark he wished to refer to was that about members of the profession having their practice taken away from them by the Inspectors visiting their clients' places. Unlike Mr. Archer he was an Inspector, but he hoped none of them had such a bad opinion of him as to think that if he went to a fellow-practitioner's client and found an animal suffering from tuberculosis or suspected tuberculosis he would be pig enough, he could not use a milder term, to suggest that he should treat the animal himself. He admitted that

this might happen in certain cases, but no legislation in the world would alter it. They could not make gentlemen of men who were not gentlemen.

Mr. HENDERSON remarked that before this 1913 Order came in force he thought he was going to have nothing to do with it, but in his district it had acted in just the other way to what Mr. Archer had suggested it would. Farmers generally had a special dread of legislation, and rather than have an inspector come about their premises they were coming to him, and he found he was getting clients that he never expected to have, simply because another practitioner happened to be the veterinary inspector. There might be something in what Mr. Archer had said, but it cut both ways.

Mr. PACK said that up to now the new Tuberculosis Order had made very little difference to him, but the question he should like to put to them was this—What cases were they to condemn? He had treated two cases where he had got a re-action up to 107, and yet in neither case was there any sign of tuberculous milk, injury to the udder, or emaciation. What ought he to do?

Mr. ARCHER: Report it as a suspicious case.

Mr. PACK: But on what grounds. If you report them as emaciated or on one of the other grounds, and the animals are slaughtered, the owner gets compensated according to the advance the disease has made, but what are you to do when there are none of these definitions present. At the same time I should not feel satisfied with letting those cows go.

Mr. DELLA GANA remarked that he was not an inspector, but only a poor practitioner, and his experience of the working of this new Order had not been very satisfactory. After going to a great deal of trouble and much observation he had reported certain cases, and the result had been he had had to meet a policeman and the local inspector, and had been told to go. He thought with Mr. Archer, that the Order would in time deprive the general practitioners of a great deal of their work. The appointment of unqualified men as inspectors he considered was disgraceful. They reported a case of suspected tuberculosis and the inspector, an unqualified man, came in and either confirmed or disapproved their opinion. It was most undignified, and he thought this aspect of the matter should be brought to the notice of the Board of Agriculture by their Societies most strongly.

Mr. ANGLIN said that his advice to them was to study this Act very carefully. The Order was on trial, so to speak, for five years, and the local Authorities were asked to appoint a sufficient and an efficient veterinary staff to carry out its provisions. That was to say, any local Authority had power to appoint men to act under the Order. He had already applied to the County Council to be appointed and it was open to every other member to do the same. There was one thing in the Act he wholly objected to, and it was this—any local practitioner who in his daily practice discovered a case of undoubted tuberculosis, was asked to report it, and he would be rewarded with the munificent sum of half-a-crown. Was that a reward or a bribe? Personally he thought the Act would fizzle out. A man had a cow, possibly a tuberculous animal. If killed, and it proved to be Johne's disease he got nothing. If tuberculous, by the time he had gone to the expense of having it tested he would find it would pay him better to send it to a knacker's yard in the first instance, and not mess about with the Act. They must also bear in mind that the Authorities had not got a lot of money to waste, and although they could spend any amount of public money on the Act they were going to use a little common sense.

Mr. BAKER thought it was rather unkind to put them all in the same category. He had frequently gone into a fellow practitioner's preserve, but he had always re-

fused to take any work out of another's hands, and hoped members of the profession had a better opinion of their fellow practitioners than to imagine that there were many who would do other than he had done.

Mr. ARCHER, referring to Mr. Pack's observations, remarked that under the Contagious Diseases of Animals Act, every inspector who had a reasonable suspicion that an animal was affected with a contagious disease was bound to report it, and they were all of them only suspicious cases until one had made a post-mortem. Tuberculin was not an official test, but it was recommended to be used with the owner's written consent as an aid to diagnosis, and if they used it at all and got any reaction, surely they must abide by the result.

The PRESIDENT remarked that when he made the observations he did in his address, he had no idea it was possible for an unqualified man to hold the position of inspector.

Mr. ARCHER: I believe there are twenty-six unqualified men acting as inspectors under the Act already.

Post-mortem specimens and cases of interest were subsequently invited, and Mr. Angwin submitted an interesting specimen of a split pastern of a horse, the result of what was commonly known as a spontaneous fracture.

The customary compliment to the President for presiding, proposed by Mr. Pack, and seconded by Mr. Archer, brought the meeting to a close.

J. ALEX. TODD, Hon. Sec.

ROYAL SANITARY INSTITUTE CONGRESS.

CONFERENCE OF VETERINARY INSPECTORS.

ADDRESS by Prof. J. PENBERTHY, F.R.C.V.S., President of the Conference.

[ABSTRACT].

I hope you will first allow me to express my appreciation of the honour of being invited to preside over this important conference. Though I do not enjoy the advantages of occupying the position of veterinary inspector, it has been my privilege to take some small part in the education of many of those who in that position are rendering valuable service to the State, and I may at least lay claim to a deep interest in all means designed for the accomplishment of the object to which your energies are specially directed. I should like to use this opportunity to offer you my congratulations on the formation of an association, the aim of which is to render your services still more valuable to the community and to obtain for your work the recognition it deserves.

I take it that we are met here in conference to-day as a section of this great Congress with the common purpose of acquiring and, may be, disseminating knowledge adapted to the improvement of the conditions under which human beings exist, in the hope of becoming better qualified to suggest and carry out measures which will render human life more secure from the dangers by which it is beset. The veterinary inspector, if he aims at the highest degree of usefulness and satisfaction, will never lose sight of the high character of his work in relation to human health. Though in a strictly professional sense, his official sphere of action may be limited to the consideration of diseases communicable from animals to man, and the means of averting such communication, the veterinary inspector, as a citizen of the world, with ideals and aspirations in nowise inferior to those which guide conscientious workers and thinkers in other spheres of life, is not called on to exclude himself from taking part in deliber-

ations on other aspects of public health. In the exercise of his administrative and executive duties, a judicial mind is essential for the most effective application of technical knowledge pertaining to his profession. His education and experience should afford him specially favourable opportunities for forming, on sanitary matters generally, sound opinions, the expression of which would often add value to the deliberations of local sanitary and even imperial authorities.

I venture to think that a much more frequent association of members of the veterinary profession with public life, would prove of advantage to the community and to their profession. Happily, evidence of a higher appreciation of his work in relation to the public is evidenced by their more general enlistment in the sanitary service. In all questions, which entail consideration of the hygiene and disease of domesticated animals, the properly qualified veterinary surgeon must occupy the position of responsibility, and even if the matters considered have reference to the relation of animal disease to human health, the determination of the condition of the animals and the circumstances affecting their health, including those necessary for preventing the occurrence of diseases in them, must necessarily rest with him, who, by virtue of his special education, his experience, and his statutory qualification, may claim the performance of such duties as his prerogative.

The duties of the veterinary inspector not infrequently involve pronouncements distasteful to those with whom it is most desirable that he should have agreeable relations. I have no intention of reading you a homily, gentlemen, but with your indulgence may I be permitted to say that, while I regard it only commonly honest for you to use every opportunity for making yourselves proficient in the professional knowledge essential to the best performance of what are often extremely difficult duties, for the most successful application of that knowledge the co-operation to be secured by the good will of those connected with the objects of your inspection is the greatest asset you can acquire. The exercise of the best tactics at your disposal are often necessary to overcome a general prejudice against inspection of any kind, and to meet individual peculiarities. I do not suggest a cringing opportunism, or that your actions should be affected by fear or favour, and am only incited to refer to this aspect of the question as a result of personal observation of the great power for good which many inspectors, who adopt the conciliatory attitude, exercise, and in rare cases, the converse.

It has been a source of great satisfaction to me, in my association with agriculturalists deliberating on cognate topics, to observe much evidence of confidence in the profession, and the desire to see them in occupation of positions to which their professional knowledge entitles them. The elimination of disease from our cattle, and the removal of the danger of communicating disease to the human subject, will be more speedily accomplished by voluntary action in conjunction with the performance of statutory obligations than by the latter alone. For instance, at present there is amongst stock-owners widespread prejudice against the use of tuberculin as a test for tuberculosis. It is certain to my mind that without this, or some other aid at present unknown, the eradication of tuberculosis will never be accomplished. I look to the intimate relations of the veterinary inspector under the Tuberculosis Order and the owners of infected herds as a means of establishing confidence in this aid to diagnosis, and an extensive voluntary adoption in the interest of the stockowner and the community.

The difficulties of the inspector may commence with the owner, but assuredly they do not end there. In dealing with such a disease as tuberculosis, as, indeed, with all others, correct diagnosis is a fundamental

essential. In this respect he cannot fail to find himself at times in a position of great delicacy. His opinion given during life is submitted to the scrutiny of post-mortem examination, and the result of any error he may make is subject to the criticism of his local authority through the chancellor of its exchequer. This work demands a high degree of professional skill and wisdom, and even in full exercise of these qualities the most skilled and wisest must be liable to risks of error in this sphere of action. That this is a matter of special interest is evidenced by the wise selection of diagnosis as a topic of discussion at this conference.

The diseases existent in Great Britain known to be communicable from animals to man, though small in number, are far from unimportant. The elimination of rabies from the category and the consequent disappearance of hydrophobia, the diminution in the cases of glanders in our horses by 75 per cent., and the control exercised over anthrax, which have all been effected in the past decade, stand in a great measure to the credit of veterinary inspection. Some other diseases, recognised as communicable but of less serious import, remain, and possibly there may be others whose relations to man are not yet ascertained, but I may venture to say that the chief interest at present centres on tuberculosis.

Five years since it was my privilege to preside over a similar conference at Cardiff, when I took advantage of the opportunity to cursorily review the position of the tuberculosis question at that period. Since that date an immeasurable amount of research work and inquiry has been accomplished, and large areas of paper have been occupied by contributions to the literature of the subject. The final report of the Royal Commission on tuberculosis has been received and discussed, with the result, I venture to think, of deepening the conviction that some portion of the tuberculosis of human beings, especially of infants and young children, owes its existence to tubercle bacilli derived from the lower animals, and principally taken into the body with cow's milk and other animal food.

The death-rate of man from tuberculosis, which the President of the Local Government Board, speaking in 1908, stated was "diminishing in this country generally, proportionately more rapidly than in any other country in the world," has continued to fall in a manner which cannot be regarded as otherwise than gratifying. The Chancellor of the Exchequer has entered the arena and, through the National Insurance Act, opened up the avenues of curative treatment. Demands for removal of the danger arising from tuberculous animals, though not less insistent on the grounds of being necessary, appear to have become more moderate and nearer to being practicable. On knowledge acquired in the interval it has been possible for some authorities to estimate, at least to their own satisfaction, the proportion of cases in which tubercle bacilli of the human and bovine types respectively are found. It has been variously estimated that in 10 to 25 per cent. of cases of tuberculosis of children under five years of age, those of the bovine type are the cause, while in cases occurring in man from fifteen or sixteen years upwards, their presence has been so rarely found in connection with his tuberculosis that, as a cause of the disease in adults, the bovine bacillus is practically a negligible quantity. Neither these figures nor the observations on which they are based have, however, brought universal conviction. There are some who persist in the view that a rapidly falling death-rate among infants from tuberculosis, and an increased consumption of cow's milk, indicate that the danger of materially curtailing the milk supply by withdrawal of the milk of tuberculous cows would outweigh the advantages now enjoyed.

The issue of the Tuberculosis Order, 1913, is perhaps the most important event to be chronicled in relation to

bovine tuberculosis and veterinary inspection. Though directly emanating from the Board of Agriculture, and, at any rate, ostensibly in the interest of the stockowner, there is good reason for believing that the real cause of its promulgation was consideration for the health of man, and we may regard it as one part of the great national scheme of campaign against human tuberculosis. I refer to the issue of this Order as the initial step, because I believe that every competent person who has made a careful study of tuberculosis in cattle and other domesticated animals, must be convinced that other and more drastic measures will be required to effect the final elimination of tuberculosis from the live-stock of this country. There can be doubt that the exclusion of cows yielding tubercle bacilli with their milk, having tuberculous udders, or being emaciated from tuberculosis, must lessen the numbers of bovine tubercle bacilli in milk consumed by human beings, and to a considerable extent diminish the risks of infection of farm animals.

It is gratifying to observe that the operations of the Order are directed to the permanent removal of the immediate and paramount source of danger to cattle and that of bovine tuberculosis in man.

Though it would be unfair to assume that any considerable number of stockowners would desire to keep dangerous cows and sell their noxious products, if they realised the danger, no form of inspection which may involve the confiscation of property which he regards as a valuable asset is likely to be pleasing; but I venture to express the opinion that considering all the circumstances, especially the outcry for drastic measures for the immediate extirpation of tuberculosis of cattle, the Tuberculosis Order of 1913 gives evidence of having been conceived and formulated at the dictates of moderation and with a proper regard for all the interests concerned, except, perhaps, in the amount of compensation, and the source from which the cost is to come. The stockowner will naturally feel that compensation should have been on a more generous scale, and it is to be regretted that it is not frankly admitted that it is in reality a matter purely of national health. It was doubtless intended to be complementary to a Milk and Dairies Act, and without the latter the Order is incomplete and less effective than if the Bill now before Parliament had become an Act. The Order cannot fail to have an educational effect of great value on the stockowner, the authorities, and the public. In view of the fact that the £60,000 annually provided by the Treasury for payment of compensation, is granted for five years only, it is not improbable that the whole cost of more radical measures, which may be enforced at the termination of this period, will fall on the owner and the local authorities. This should be an incentive to local authorities to carry out the provisions of the Order, and to the stockowner to make every attempt to purify his herd, while even the small modicum of compensation is available.

Notwithstanding all the investigation by research and ordinary observation, results of which have been recorded, it cannot be stated that opinion on all essential points is unanimous, or that all the problems in connection with the relations of tuberculosis in man and cattle are yet satisfactorily solved.

In the current number of a journal devoted to State medicine, appears the statement of a well-known bacteriologist: "Public authorities have generally been in a state of indecision owing to the controversies which have divided scientific men." Doubtless this is true. I venture to say that the public have some reason for thankfulness that such variety of opinion has on occasions existed and exercised such an influence. We recall the statement of the medical officer of health, who advised his authority that tuberculosis of cattle could be eradicated in twelve months by the means successfully

adopted in the case of pleuro-pneumonia, but omitted to say that in order to effect this desideratum it would be necessary to eliminate the bovine species in this country. Also we have in mind the advice given within the past five years by the medical officer of health of one of the greatest cities the world has ever seen, "that every cow in the country should be subjected to the tuberculin test, and that no milk of any tuberculous cow should be allowed to be sold for human consumption." It was not stated that the cost of applying the test on the first occasion would be from a quarter to half a million pounds, and that, as this would mean the immediate withdrawal of 500,000 cows, it would possibly considerably reduce the cost of the second retesting, which would be necessary at least at the end of each six months for years to come. The effect of the withdrawal from our national food supply of 250,000,000 gallons of milk was not even referred to. The day for such extravagances is past, the scope of the Tuberculosis Order, 1913, as a complement to a Milk Bill, represents the limit of the sphere of operations which are consistent with our present knowledge, and are practicable at present.

There are, however, still many problems awaiting solution, and on which scientific opinion is widely divided. Among the more important questions are those of immunity, the transmutability of the bovine and human bacilli, and the ultimate effect of the early extirpation of the bovine bacilli. It is not necessary to reject any evidence, indicating that bovine tubercle bacilli taken with cow's milk are responsible for tuberculosis of children, to suggest that it is desirable that investigation on these and other points should proceed while the preventive measures dictated by our present knowledge are in operation. There is, perhaps, at the present time more general agreement on the following points: that bovine bacilli, taken in sufficiently large doses, or in smaller doses frequently, by infants and young children, are responsible for tuberculosis in a certain proportion of cases occurring at this age; while nearly the whole of the cases in man after the age of 16 are traceable to infection from a human source. It is stated on high authority that more than 90 per cent. of our population above 16 years of age are distinctly tuberculous, and that 98.09 per cent. of all fatal cases of tuberculosis are due to the bacillus of human type.

If it be maintained that tubercle bacilli of bovine origin do not, after prolonged residence in man, acquire the characters of tubercle bacilli of the human type, the danger of acquiring tuberculosis from eating animal flesh cannot be great, as, after 16 and throughout the flesh-eating periods, tuberculosis in which bovine bacilli are found is so rare as to be practically negligible as factors in the tuberculosis of adult human beings. This suggests that either the tubercle bacilli in flesh are so few or feeble as to be ineffective, or that after the age of 16, immunity, hereditary or acquired, against the fatal effects of the bovine bacillus prevails. The experiments reported on by the last Royal Commission on Tuberculosis indicate that the results of infection depend on the virulence of the individual virus, the dose received by the subject, and the resistance of the subject. In a communication to *The British Medical Journal* of February 1st, 1913, referring to an observation of over 6,000 cases of tuberculosis, it is stated:

"That there seems to be little doubt that a mild infection of bovine bacilli in the human body, such as neck glands by way of the alimentary canal, will protect against infection by human bacilli, and it is most probable that a large number of people are immunised by having been infected in early childhood by bovine bacilli through milk or food."

This view of the subject has been more or less freely expressed for some time, and I venture to think it

worthy of further consideration. We do know that the incidence of some diseases in adult life is materially affected by the fact that immunity is acquired as a result of an attack in youth.

Prof. Orth, Virchow's successor, at a recent meeting of the *Berliner Medizinische Gesellschaft*, maintained that the transmutability of the human type of tubercle bacillus into the bovine type had been proved by von Eber, and drew attention to his own experiments carried out in 1906, in which he claimed to have shown that a primary local infection with inoculated bacilli could create a heightened latent susceptibility to future infection, and that under such circumstances pulmonary phthisis was the usual sequel, and that a bovine infection contracted in infancy might play a similar part in the development of the disease in adult man was no unreasonable speculation. Here we have a directly divergent view based on experiments seven years ago. At the same meeting Weber, a member of the Imperial Health Commission of Germany, stated that post-mortem reports and experimental investigation had shown no parallelism in the incidence of the disease in man and cattle, nor were there any marked differences in the statistics of countries in which cows' milk was not the staple diet of bottle-fed infants and children. He further adduced the fact that of 280 children known to have drunk the milk of tuberculous cows, only two, and both these were cases in which the cervical glands were involved, had the disease subsequently, and that seven years later, during which time they had been under direct observation of the Board of Hygiene, not one of the 280 had died of tuberculosis.

These statements are not brought forward as argument that the procedure adopted by the authorities—which it is the duty of the veterinary inspector to carry out, is valueless or should be postponed, but to indicate that there is further work for research, ordinary observation, and enquiry; that still there are problems requiring solution; that they cannot all be solved through the microscope or with the guinea-pig; but to indicate that the enthusiastic veterinary inspector, acting in conjunction with the medical officer of health or independently, has it in his power to accumulate information by the method of direct observation and enquiry, and by recording it, to add materially to that store of knowledge by which the solution of some of the problems can only be effected. I venture to suggest the record of widespread observation of the events occurring to infants and children known to have ingested milk of cows discharging tubercle bacilli from a tuberculous udder. The results of a few such observations have, I believe, been published, but, in order to be of high or, indeed, of any statistical value such records must be numerous. Further, it has often been stated that among persons in close attendance on tuberculous cows from youth onwards and running great risks of ingesting and inhaling more or less constantly, bovine tubercle bacilli, the incidence of tuberculosis is, at least, no heavier than that among other classes of the community not exposed to such risks.

The question of natural and acquired resistance to serious infection is to the veterinary profession and the stockowners of special interest, in view of the possible discovery of a means of immunising cattle, and rendering them innocuous to their own and other species. With the aid of an easily applicable and safe method of establishing an effective resistance to infection, the veterinary aspect of tuberculosis would be easily solved. The study of this subject, however, has even wider significance and a far greater object in view, for if it should be proved that a considerable proportion of the 90 per cent. of the population, above sixteen years of age, which are stated to be distinctly tuberculous, owe their freedom from its fatal or serious effects to the in-

gestion of small doses of bovine tubercle bacilli during infancy or childhood, it would become necessary to consider the advisability of using the bovine bacillus, under control, as a means of providing immunity; and the probable effect of extirpation of tuberculosis in cattle, before tuberculosis due to infection by bacilli of human type is brought under control.

VETERINARY ASSOCIATION OF NEW SOUTH WALES.

PRESIDENTIAL ADDRESS.

By Mr. S. T. D. SYMONS, M.R.C.V.S.

Gentlemen,—It is just a year since the Veterinary Association of New South Wales was brought into existence, and, having the honour to be elected as your first President, it now affords me pleasure in delivering this address, a procedure which I believe is an annual occurrence in relation to societies of this nature.

As most of you now present are aware, this is not the first effort of veterinarians in this State to band themselves together in the interests of their profession, for as long since as the year 1894, a Veterinary Medical Association was established. It struggled along fairly actively for a period of three or four years, after which it remained moribund, until the steadily growing feeling of unity amongst the members of our profession resulted in a meeting being held at the Veterinary School, Sydney University, on May 10th of last year, when it was decided to resuscitate the Association.

Before passing on to the progress of our Association, I feel sure you will accord with me in brief reference being made to the old Association. Amongst members were Messrs. John Stewart and John Pottie, veterinarians of the day, who were well and favourably known, and whose decease is much regretted; Edward Stanley, who although still with us, is leading a life of peaceful retirement after performing what must be recognised as good work for the State, often under serious disabilities. Of the others, some have gone to distant climes, many are still amongst us, and several are present here to-night.

It is a matter for congratulation to us all that I am able to remark that as regards membership, our Association shows very excellent progress. With 10 members at its formation, a rapid increase in numbers occurred, until a total of 33 was reached, with three Associates. Two members have resigned during the year owing to their leaving the State, but there are other nominations to come before us, which will strengthen our ranks yet further.

During the first year of its existence the Association may be said to have thoroughly justified its formation by its action in regard to matters of such prominence as the endeavour to bring before the legislature a much needed Veterinary Surgeons' Bill; representation of the profession on the Tuberculosis Advisory Board; and the formation of an Australasian Veterinary Association. It has thus evidenced its desire to advance the status and power of the veterinary profession.

Referring to the Veterinary Surgeons' Bill, as far as my memory serves, such a measure was discussed by the old Association, but I believe it was decided that the introduction of legislation of this nature to Parliament was at the time premature. With the general growth of the State, and with the establishment of a Veterinary School at the University, it seems a matter for extreme regret that no such legislation has yet come into operation to protect the interest of those now professionally engaged as well as those who will shortly qualify from the aforementioned Veterinary School. Moreover, at

the present time, unwarranted mortality amongst animals no doubt occurs, and cruelty is rife, from the widespread empiricism that exists. The stockowner as a rule is not in a position to recognise between the veterinarian who is properly qualified, and perforce in some degree humane, and the charlatan who from lack of suitable training, inflicts indescribable tortures on the dumb creatures which he is called upon to treat. Such legislation, therefore, would be in the interests of stockowners also.

Duly qualified veterinarians are not numerically strong in New South Wales, and as in many instances they are far apart, any concerted action in the past has been difficult of accomplishment. To their credit, however, it must be recorded that although certain prior disjointed action had taken place, in the year 1909 meetings were held which resulted in a Veterinary Surgeons' Bill being drafted, some of those attending coming very long distances. This is the Bill we now strongly desire to become law. Deputations from this Association have waited upon the Honourable the Minister for Agriculture, by whom the measure will be introduced to Parliament, pointing out the disabilities the profession and stockowners now suffer, and urging that early action may be taken. Your Council also have had several meetings for the consideration of certain amendments thought to be necessary, and must be thanked for the very careful attention bestowed on the subject. Gentlemen, it will rest with you to keep this matter prominently before your Association, and exercise extreme vigilance in the endeavour that a satisfactory ending may be arrived at.

I will now say a few words as to the future prospects of veterinarians in this State, and I consider my remarks are equally applicable to the other portions of the Commonwealth, as well as to New Zealand. We cannot all aspire to be Administrators of Territories, or Under Secretaries for Agriculture. It appears to me, however, that with your professional rights protected by satisfactory legislation the future outlook is bright. As your abilities become to be better recognised, a much greater number of varied official positions will be created, and I do not think the time is very far distant when the heads of Government departments in the different States dealing with Stock matters will be veterinary surgeons. Other factors in advancing our prospects are the generally improved values for all classes of stock, closer settlement, with consequent agricultural development.

Together with Professor Stewart, it was my privilege to be selected as a representative of the Association on the Tuberculosis Advisory Board. It is perhaps needless to mention that every courtesy was extended to us by its members, and I may perhaps be excused in remarking that I believe our particular knowledge was of great assistance to the Board in its deliberations. In recognition thereof, I may state that the Professor was appointed a member of the Sub-committee to draft a report on the subject of "Milk," myself acting in a similar capacity in relation to "Meat."

Several of the members of this Association attended the Congress for the advancement of science held in Melbourne in January last, Professor Stewart being appointed to represent our interests. I do not think that I shall be out of place in mentioning that as a step in the general advancement of the profession, it has been decided to make veterinary subjects a separate section in the future, instead of it being a sub-section of Agriculture as in the past. Of more particular interest to us, however, is that it was then also decided to form an Australasian Veterinary Association, the meetings to be held at the same time and place as the Science Congress, also that our Association should undertake the arrangements in connection with its formation. This has been referred to, and, as the initial expenditure is

not large, it can be met out of our funds. That the action as indicated is a step in the right direction I think you will all agree, as tending towards a healthy professional co-operation throughout the Commonwealth and the Dominion of New Zealand. It is believed also that it will be a forerunner to the formation of many local societies.

I am pleased in being able to inform you that the finances of the Association are in a satisfactory condition.

On the professional side, two papers have been read at our meetings, and thanks of the members are due to those who brought them forward.

Dr. Dodd's paper was on "Osteomalacia"; Mr. Baker's on "The Lymphatic System of the Horse," a series of well executed diagrams thereon lending much additional interest.

Addresses were given by Mr. Sanderson on the question "Does the Bang System lower the resistance of cattle to tuberculosis when exposed later to infection," and by Mr. Henry on "Variegated Thistle as a poison plant."

All these matters were well discussed at the time by members present.

On the social side, the Association held a most satisfactory dinner in November of last year, a forerunner of what it is intended shall be an annual event. More recently we were able to welcome at a pleasant informal gathering the veterinarians from other States present

in Sydney, at a Conference in connection with the improvement of horse breeding by certification of stallions, and other matters.

In addition to those important matters already referred to, requiring the careful attention of this Association during the coming year, there are others of equal moment that might receive your consideration. I refer as instances to: Veterinary representation on the Meat and Abattoir Board. Similar representation on the Health Board. The desirability of the appointment of veterinary surgeons in charge of inspection at abattoirs, and to any subject of an allied nature that may appear on the horizon during the period.

In conclusion, gentlemen, I feel that the second year's progress of this Association will not only be equally successful with the past, but that it will be more so, and my very best wishes are to that end. My position as President has been rendered easy by the assistance of an energetic and capable secretary, and the kind attitude assumed on all occasions by members towards the Chair.

The officers elected for the coming year were:—

President.—Mr. S. T. D. SYMONS, M.R.C.V.S.

Vice-President.—Prof. T. D. STEWART, M.R.C.V.S., B.V.Sc. (Sydney).

Hon. Sec. & Treas.—MAX HENRY, M.R.C.V.S., B.V.Sc. (Syd.) 56 Bridge Street, Sydney, N.S.W.

Presentation to Sir C. J. Nixon.

The Principal and Staff of the Royal Veterinary College of Ireland recently presented a loving cup—a mother cup, of Irish make—to Sir Christopher Nixon, Bart., LL.D. Sir Christopher at the same time received the following letter from the Principal:—

“Dear Sir Christopher,—Will you kindly accept the accompanying loving cup from the Staff of the College with our affectionate regards and profound esteem? As you will see, we all unite in asking you to accept this token of our appreciation of all you have done, not only to place the College on a secure foundation as an educational centre, but in securing for the Staff State recognition and a permanent future. We all recognise how ungrudgingly you have worked and how the interest of the College and its Staff has been ever your interest also; but apart from that, we are anxious in some little way to show to you that we all have for you an affectionate esteem. The new change in the governance of the College, fortunately, does not interfere in any way with your connection with the College, and we all hope that you may long continue to take an active share in directing the destinies of the College. Please look upon this loving cup as a symbol—a mere outward token of our esteem and regard.—Believe me, dear Sir Christopher, yours very faithfully, A. E. Mettam, Principal.”

The following reply was received from Sir C. J. Nixon:—

My Dear Principal and Members of the Staff of the Royal Veterinary College of Ireland—I do not know how to thank you and your colleagues on the Staff of the Royal Veterinary College of Ireland, not merely for the extremely handsome presentation which you sent to me, but for the affectionate appreciation which you have all expressed of what I have been able to do in promoting the interests of the College. Your loving cup will be regarded as an heirloom which will be always associated with the traditions of my family in generations to come.

To those who have followed, as doubtless you have done, the marvellous progress of the College, the steady increase of the number of its students, the high order of the teaching given in the various departments of veterinary medicine, and the discipline maintained during the entire period of its existence, you may naturally ask to what is our success due.

First, that the College was an urgent necessity for Ireland; second, that from the year of its foundation it fulfilled with increased efficiency the purpose for which

it was founded; third, that it steadily established a claim on the State which could not be ignored, namely—that in the reorganisation of the Department of Agriculture, use must be made of a Veterinary College to help in co-ordinating all the elements which tend to make a State Department perfect in all details, including especially research work, such as will effectively aid the agricultural progress of the country.

You are good enough to point out that the change in the government of the College will not interfere with my connection with it in the future. That is so. My position in the future will enable me to look after your interests and to obtain for you a recognition of those services, which so materially helped to place the College in its present high position, services which the Department of Agriculture and Technical Instruction for Ireland has pledged itself to deal with, not merely equitably but liberally.

Again thanking you most cordially for the expression of your esteem and affection.—Believe me, gentlemen, always your sincere friend,

C. J. NIXON.

30th June, 1913.

Messrs. Weir, of Grafton Street, Dublin, supplied the cup, which is engraved with the crest of Sir Christopher Nixon and the names of all the members of the staff.—*Dublin Evening Mail*.

Royal Veterinary College.

Lord Moreton presided at the annual meeting of the Royal Veterinary College, on Tuesday. There were also present Lord Harlech, Lord Bathurst, Sir John McFadyen, Principal of the College, Major-General Pringle, Director-General Army Veterinary Department, and Sir T. Elliott. The report for the year showed that the income had exceeded the expenditure by £1,223 14s. 11d. as against £52 19s. 7d. in the preceding year. The result had only been brought about by a reduction in the salaries of members of the College staff, which the governors would now be called upon to make good in the form of a bonus. Mr. A. Brassey, a governor, in moving a vote of thanks to the Chairman, said that during the past year the Principal had been to India to study foot-and-mouth disease, and the College was already studying tuberculosis and other diseases in animals. If the College were better known it would not have to curtail its exertions through want of funds.—*The Times*.

Royal College of Veterinary Surgeons.

EXAMINATIONS IN LONDON.

At the meeting of the Board of Examiners held in London on July 7th for the Written, and on July 8th, 9th, and 10th for the Oral and Practical Examinations, the following gentlemen passed their Final Examination:—

Mr. W. A. Austin	Mr. V. J. Hare
C. E. W. Bryan	H. Hicks
J. Blackburn	W. Kendrick
R. T. Davis	A. V. Nicholas
C. Davenport	A. A. Pryer
H. W. Dawes *	J. M. L. Penhale
G. van de W. DeKock	J. Southall
R. Daubney *	W. L. Sheffield
G. O. R. Grey	A. R. Symthe
D. C. Greene	G. M. Vincent
A. Hoskin	J. A. Ward

Marked thus * passed with Second Class Honours.

EXAMINATIONS IN EDINBURGH.

At the recent Examinations held by the Court of Examiners in Edinburgh, the following students of the Royal (Dick) Veterinary College passed their Third Examination:—

Mr. N. Brear *	Mr. D. Marshall *
T. Dalling	T. M. Mitchell
J. W. Hayes	J. J. Plunkett
G. C. Lancaster	R. Simpson
R. G. J. Lake	B. van der Vijver

The following passed their Second Examination:—

Mr. W. H. Dennett	Mr. W. Hay
R. Dalling	C. K. Lomas *
J. Edgar *	B. Philp
W. Harley	R. K. Porteous

The following passed their First Examination:—

Mr. T. Bannatyne	Mr. J. Judge
A. Noel Metcalfe	E. H. Milner
N. Bisset	E. C. Nelson
J. D. Coutts	J. R. Rider *
J. S. Carewal	A. Rouse
G. Howie *	C. V. Watkins
J. Knox Irvine	

Marked thus * passed with Second Class Honours.

EXAMINATIONS IN DUBLIN.

At the recent Examinations held by the Board of Examiners in Dublin, the following students of the Royal Veterinary College of Ireland passed their Final Examination and were registered Members of the R.C.V.S.:—

Mr. J. J. O'Neill	Mr. J. J. Mills
T. G. Browne	J. J. Pomeroy
M. P. Hatch	T. K. Reddin
J. J. Hegarty	C. M. Stewart
J. P. McNally	M. Twomey

The following passed their Third Examination:

Mr. J. Campbell	Mr. P. J. Hayes
S. O'Donel	H. Jewell
E. H. Wyly	M. J. Killelea
W. A. Buchanan	H. J. Lowe
W. G. Clarke	P. J. Mulcair
F. J. Daly	O. D. Neary
H. Dolan	J. O'Carroll
C. P. Fisher	W. P. Power
S. Flood	M. J. Ryan

The following passed their Second Examination:

Mr. J. J. English	Mr. W. H. Heaney
T. J. McDonald *	J. J. Mullaney †
J. A. Brew *	T. F. O'Connor
J. M. Cullhane	M. A. Sexton
T. A. M. Finch	T. F. Tunney †
J. J. Fitzsimons	M. A. Murphy

The following passed their First Examination:

Mr. J. J. Clune	Mr. W. Forde
P. J. Cooney	E. V. Kelly *
H. C. Evans	J. Malone
T. C. Hall	E. S. W. Peatt
J. J. M. Barry	J. A. Power
J. Bell	W. Reidy *
J. Brosnan *	W. J. M. Rouse *
J. J. Condon	C. B. Ryan
F. H. Doyle	W. L. Sinton
M. Farrelly	D. P. White

Marked thus † passed with First Class Honours.

Dispute about a Mare.

Sheriff Macleod, in the Linlithgow Sheriff Court, heard proof in an action by William Braes, veterinary surgeon, Linlithgow, who sued James L. Meikle, farmer, Upper Bonnytown, Linlithgow, for the sum of £31 10s., being the price of a black mare sent by him to Mr. Meikle on trial on 28th November, 1912, and which, he maintained, was sold to Mr. Meikle on or about 11th December, 1912, the mare having died on 31st December, before the price was paid. The following interlocutor in the case has now been issued:—

Linlithgow, 11th June, 1913.—Finds, in fact, that (1) towards the end of November, 1912, the defender was on the lookout for a horse suited for his general farm work, and on the 28th of that month the pursuer sent the mare labelled, which was the pursuer's property, to the defender's stable in order that the defender might make trial of its suitability for that employment; (2) the mare remained in the defender's possession until its death on 31st December, 1912; (3) when the pursuer sent his mare to the defender's stable he set no time for the termination of the trial, but after an interval of time, coming to hear of another possible purchaser, he entered into communication with the defender with the view of getting an early definite reply from him as to the purchase or non-purchase of the mare; (4) the pursuer has failed to prove that he at any time arranged with or intimated to the defender any limit of time at the expiry of which, without return or without notice of rejection, the defender was to be regarded as the purchaser of the mare. The mare was not at any time in the possession of the defender under any condition as to limit of time for trial; (5) owing first to the condition of the weather, and latterly to the health of the mare, the defender had not, while the mare remained in his possession, a reasonable opportunity of making trial of its suitability for his requirements; (6) the defender never agreed to buy the mare. Before it took ill he was not satisfied as to its suitability. When it took ill he decided to wait till it got well again before

thinking further as to the prudence of making an agreement to buy. It never got well enough for that purpose; (7) the pursuer and the defender communicated with each other on the question of price, but never came to an agreement on that matter; (8) while the mare remained in the defender's possession the defender and his servants gave her both in health and in sickness all that watchful care which a prudent man would give to his horses; (9) the defender was in no way to blame either for the sickness or the death of the mare. Finds in law (1) that there was not completed sale of the mare; and (2) that the pursuer is not entitled to any decree against the defenders there-after assuages the defender from the conclusions of the initial writ; finds the defender entitled to expenses on lower scale, and remits the account thereof when lodged to the auditor to tax and to report.

(Signed) HECTOR MACLEOD.

In a "note" his lordship adds:—(a) No mare ever came nearer the selling point without actually touching it, and it has, therefore, been quite easy for each party honestly to persuade himself that its loss ought to fall on the other. At the same time, I have as clear a view as is possible for erring mortal that there was no completed sale. Let me just mention one or two points that seemed of special interest—(b) on the interesting controversy as to the course of events between the 9th and 13th December, I have a very distinct preference for the view presented by the defender as being an accurate one; (c) when the parties had the important talk about the price the mare was "off its feed" to the knowledge of the defender; (d) the pursuer's interest in the carcase is amply accounted for by his professional desire to verify his diagnosis; (e) I draw no inference from the fact that during the period of temporary convalescence the mare remained in the defender's stable. It is quite a good point for presentation in argument, but any inference from it would be unwise; (f) on Thursday, 16th December, the mare had so far recovered that the pursuer left her without any intention of returning to give her further medical attention. Elder (defender's second hand) was the man who had special charge of the mare. He was a man in whose watchful care of horses both the pursuer and the defender had, with excellent reason, the most perfect confidence. What he and Shanks and the defender did or did not do for the mare during the period between the 16th and 23rd December must be the subject of most careful scrutiny. On the other hand, they must not be judged by what happened later. My conclusions are set out in findings 8 and 9; (g) the defender made a point of seeing the pursuer on Monday, 23rd, to report to him the condition of the mare. The pursuer saw mare on 24th, and found her "far from well." She got gradually worse, and died on 31st December from "water on the chest"; (h) the mare was in perfect health when the pursuer sent her to the defender's stable on 28th November. (Intd.) H. M.

Alleged Cruelty at the Horse Show.

Arthur Hudson, a groom, living at Anlaby Road, Hull, was summoned before Mr. Mead at the West London Police Court on Wednesday, 9th inst., for cruelly ill-treating a horse at the Horse Show at Olympia. The defendant did not appear, but sent a letter in which he admitted he gave some mild ginger to a horse, and that he had seen hundreds of horses treated in the same way.

Mr. Oswald Hanson, who prosecuted for the Royal Society for the Prevention of Cruelty to Animals, stated that the operation which the defendant performed on the animal—a back Shetland mare—was known as "gingering," and was, he was afraid to say, somewhat common in cases where horses were to be exhibited for prizes or shows. The defendant was employed at the Horse Show at Olympia by a Mr. Llewellyn, and he

was seen by the Society's inspector to administer some chewed ginger to the horse before taking it into the ring.

Evidence having been given by an inspector of the Society and others,

Mr. Mead said it was a serious case, and adjourned the summons in order that the defendant should attend and also the owner of the horse.

On Wednesday, 16th, before Mr. Mead at West London Police Court on an adjourned summons.

Mr. Leslie Smith appeared to prosecute; and the defendant was represented by Mr. Bickmore, instructed by Mr. G. E. Mew.

Inspector Knight repeated the evidence he gave at the last hearing.

Alexander Piesse, M.R.C.V.S., described the effect of the ginger on the horse. In cross-examination, the witness admitted that ginger was administered medicinally, but in a different manner.

For the defence, Mr. Albert Howard Llewellyn, of the firm of Llewellyn and Co., Ltd., Walsall Saddlery Works, Walsall, said the mare belonged to him. It was a toy pony and was only entered in the show for the purpose of advertisement. The defendant was a very kind man, and witness felt sure he did not consider he was doing anything cruel to the pony.

In reply to Mr. Leslie Smith, the witness admitted he had sent a letter to the Secretary to the Society for the Prevention of Cruelty to Animals in which he asserted that far crueller things than "gingering" were done to horses at the Horse Show, and he instanced the use of sharp spurs and bits in the ring, and the practice of "nicking" under the tails of horses. He pointed out that "nicking" had a permanent effect on the animal.

The defendant, giving evidence on his own behalf, said that he only used the ginger medicinally, and he had known ginger to be used on hunters after a day's hunting. In reply to Mr. Leslie Smith, he denied that the ginger made the animal sprightly or restive.

W. F. Wright, M.R.C.V.S., of Malvern Road, Acton, said that it was a common practice to use ginger with horses, and he had used it hundreds of times. He failed to see that there was any cruelty in it.

Similar evidence was given by H. Mitton, M.R.C.V.S., of High Street, Brentford.

Mr. Mead fined the defendant 40s., with £2 4s. costs.

A similar summons was taken out against Ernest Knight, professional driver, of Church End Paddocks, Willesden, for ill-treating a horse at the Horse Show by administering an irritant.

Mr. Hanson said that this was a worse case than the former one, as the defendant gave the horse capsicum, which was essence of cayenne, and the animal must have been caused intense pain.

The defendant said he had no idea it was cruel to the horse, and it was to no interest of his to treat the horse in the way he did.

Mr. Mead, in passing a sentence of six weeks' imprisonment with hard labour, said that the defendant was guilty not only of gross cruelty, but of fraud upon the Horse Show authorities.—*The Times*.

The Dogs (Protection) Bill.

The consideration of this Bill, adjourned from Wednesday 9th, was continued on 16th inst.

Standing Committee A of the Commons having struck out the operative clause, which proposed to enact that it shall be unlawful to perform any experiment of a nature causing pain to any dog either with or without anaesthetics. The question was raised whether a Standing Committee could thus dispose of a measure the principle of which had presumably been affirmed by the House of Commons on second reading, and the Committee adjourned in order that the Chairman, Mr. Eugene Wason, might consult the Speaker on the point.

Amendments of a restrictive character had previously been carried against the promoters, and a further amendment was carried by 13 to 12 striking out the words "either with or." Sir F. Banbury, who was in charge of the Bill, was thereupon asked if he would withdraw it. He replied that he hoped to be able to induce the House of Commons to restore on the Report stage the words which the Committee had struck out.

Mr. ELLIS GRIFFITH supported an amendment, in the name of Sir P. Magnus, to add after "anaesthetics" the words "except on such certificate being given as is mentioned in the Cruelty to Animals Act, 1876, that the object of the experiment will be necessarily frustrated unless it be performed on a dog, and that no other animal is available for such experiment." The amendment was carried by 17 to 12.

The CHAIRMAN having put the question that the clause as amended stand part of the Bill, a division was challenged, with the result that the whole clause was struck out by 16 to 13.

Sir H. CRAIK asked what the promoters now intended to do, and Sir F. Banbury repeated that he would endeavour to get the clause put back.

The CHAIRMAN said it was evident that it was no use going on. He quoted the case of the Single School Areas Bill, where the Committee decided that they could not with advantage proceed further with the Bill; in that case that course was approved by the House.

Sir F. BANBURY, after submitting that the precedent cited was not on all fours with the present case, urged that it was a bad precedent that a Grand Committee with only between 20 and 30 members present should be able by a chance vote utterly to defeat a Bill the principle of which had been affirmed on second reading, and to deprive the House of Commons of the opportunity of expressing its opinion on the Report stage. It had, he said, been laid down that every Bill that went to a Grand Committee must have a Report stage.

Eventually the Committee adjourned till Wednesday next, it being understood that the Chairman, accompanied by Lord Hugh Cecil, would meanwhile consult the Speaker as to the proper procedure.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, July 11.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

Lieut. R. L. L. Hart resigns his commission. Dated July 12.

July 15.

SPECIAL RESERVE OF OFFICERS.
ARMY VETERINARY CORPS.

F. Roche, late Cadet Royal Veterinary College of Ireland, O.T.C., to be Lieut. (on probation). Dated July 16.

OBITUARY.

JOHN LYONS, M.R.C.V.S., Mallow, Co. Cork.
Graduated, Edin. May, 1889.

Mr. Lyons died on July 3rd from syncope, following acute gastric colic. Aged 52 years.

EDWIN SUMMER, V.S., Flush, Heckmondwike, Yorks. died on 14th July from cancer of the liver. Aged 64 years.

The death occurred suddenly on Thursday, 10th inst. at East Sheen, Surrey, of Mr. RICHARD ATHERTON NORMAN POWYS, who had been for 37 years, and until his death, secretary of the Royal Veterinary College, Camden Town. Mr. Powys was in his 70th year, and had been in ill health for some time. The immediate cause of death was heart failure.

Mr. Powys had been obliged, owing to failing health, to resign his appointment about two months ago, but until his successor, Mr. Thomas C. Wight, Clerk to the Edinburgh and East of Scotland College of Agriculture, was able to take up his duties, Mr. Powys had carried on the work. He was at the office as lately as Monday, 7th inst. He had served under four or five Principals, including Prof. Simonds, Prof. Robertson, Sir George Brown, and the present chief, Sir John M'Fadyean.

Mr. Powys, who was greatly respected in the veterinary profession, with which he had been so long connected at Camden Town, was the only surviving son of the late Rev. the Hon. Atherton Legh Powys, rector of Tichmarsh, Northants, and a grandson of the second Lord Lilford. His wife, a daughter of Mr. H. Hussey, died eight years ago, leaving a son.

The funeral was on Saturday, 12th inst., at Kensal Green Cemetery.

The death is announced of Dr. Schindelka, Professor of Pathology and Therapeutics at the Veterinary School of Vienna. He was widely known in connection with diseases of the eye and skin in animals—being generally regarded, in fact, as the first living authority upon veterinary dermatology. He also devoted much attention to physical methods of diagnosis, and was the inventor of the first equine laryngoscope.

The deaths are also announced of Dr. Schlamp, formerly Professor of Pathology at the Veterinary School of Munich, and author of several works in wide vogue upon the Continent, and of Dr. Hatsukuma Tokishige, ordinary Professor of Animal Pathology at the University of Tokio, and Director of the Imperial Institute of Epizootic Diseases at Nishigahara, near Tokio.

TUBERCULOSIS ORDER, 1913—FEES.

Sir,

It may interest some of your readers to know that under the new Tuberculosis Order the Somerset County Council has fixed the fee of 5/- for each post-mortem. I am not aware that the veterinary inspectors were consulted on the matter, and I consider the fixing of such a fee an insult to the veterinary profession generally. Some of the other fees are equally bad.

It is quite time some move was made in the matter, and I should suggest a meeting of all the veterinary inspectors for the county to discuss the subject.—Yours truly,

Wincanton, July 15.

J. R. ROBINS.

ON SWINE FEVER.

Sir,

I am very pleased to now have the support of the whole world in this matter. The three great troubles with pigs are cecci, strongyli, and poisons. As to red soldier being diagnostic, I will bring dozens of cases to prove that pigs which have been poisoned invariably show this symptom. In snuffles arising from strongyles or cocci, one finds lesions in the lungs in some cases, in the bowels in others. Typhoid is practically wiped out if ever it did exist. Influenza or coccidiosis of pigs we know very little about. In fact as far as I can gather from laboratory work, we always harbour this pest. It is only when it reaches an infective stage through coughing or discharges that we infect each other. I again give my opinion that slaughter will never eradicate Swine Fever—if you accept the term in its proper reading.

GEO. UPRON.

VETERINARY ETIQUETTE.

Sir,

May I ask through your paper if it be "veterinary" etiquette for a M.R.C.V.S. when replying to a nameless advert. for "a qualified assistant" to give the names of his references before he has obtained the name of the nameless advertiser. I am aware that in ordinary society it is either ignorance or a breach to make use of anybody's name to a nameless person.—Yours truly, "PERPLEXED."

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1307.

JULY 26, 1913.

VOL. XXVI.

NEXT WEEK'S MEETINGS.

The first three days of next week are full of important meetings in London. On Monday afternoon, at the Holborn Restaurant, Veterinary Inspectors will meet and compare their experiences of the Tuberculosis Order, the discussion of which should be very valuable. The "National" meetings will follow upon Tuesday and Wednesday. All we need say of both gatherings to-day is that we hope the attendances will be worthy of the importance of the subjects to be discussed.

CLINICAL REPORTS.

To-day we publish several clinical reports which, taken together, well show how greatly practitioners may aid their fellows by recording their experiences. Mr. Tudor Hughes' case bears a two-fold lesson. It illustrates the danger of neglecting canker of the ear—an affection which, in its milder forms, is often too lightly regarded in dogs, and especially in cats—and it records the discovery of a parasite not generally regarded as common in England. In the latter connection it must be remembered that the *Linguatula teniodes* may exist, as in this case, without causing appreciable symptoms, that its *habitat* is seldom examined post-mortem, and that it may therefore be much more frequent in country dogs here than we imagine. This article, then, raises a problem, and so does another one. Mr. Maguire's "peculiar case" seems not to be a very rare one in the district in which it occurred—but what is it? It may possibly be an abortive form of black-quarter; but it is far from certain that it has anything to do with that disease at all. Mr. Maguire invites comments, and it will be very interesting if we find that other practitioners have seen similar cases.

But how much practitioners do see, and how little they record! Seven years ago, at the "National" meetings, Bang gave us an account of John's disease, and many men present recognised its clinical and post-mortem features as coming within their own experience. They had seen cases, had recognised their peculiarities, but had allowed them to go unrecorded. That example should have taught us the wisdom of recording peculiar cases, but it does not seem to have done so. No one knows how many such special conditions may exist, recognised by some clinicians, yet unmentioned in our literature. But we all know that while the bulk of practitioners keep their experiences to themselves, veterinary science will never advance as it should.

DISEASE OF MIDDLE EAR: LINGUATULA TENIODES IN NASAL CHAMBER OF AN OTTER HOUND.

Subject.—An otter hound, about six years old.

History.—This hound was suddenly taken ill, and noticed to be suffering from inco-ordination of movement, carrying the head lowered slightly towards the left side.

With treatment the staggering got better, but the inclination of the head became more pronounced, and circular movement towards the left side set in. There was an advanced condition of canker of the ears, worse in the left ear, which had been under treatment by the huntsman for some time.

As the carriage of the head became worse, and the circling movement more aggravated, and the prognosis from the first unfavourable, the hound was killed.

Post-mortem.—On splitting open the head a female specimen of *linguatula teniodes* was found in the right nasal chamber. The parasite was fully matured, about $3\frac{1}{2}$ inches long, and though the hound had been killed two days previously, was still alive and showed slight movement of the head and tail when placed in warm water. The external auditory meatus of the left side presented indications of long standing disease, being crammed with inspissated discharge, and the lining membrane much thickened. On opening the middle ear, a small quantity of sanguinulent effusion escaped, the membrane of the cavity was inflamed and the tympanum much thickened, with a layer of inspissated discharge adherent to its internal surface. There was discharge, with thickening of the external meatus present in the right ear, but the middle ear of that side was normal.

Remarks.—The head of this hound was opened to examine for suspected brain disease, and the finding of the *linguatula* was rather surprising, as there had been no clinical symptoms to indicate its presence, or any other nasal trouble, and there were no nasal lesions. How the hound became infected it is impossible to say, as there is no history ascertainable of his having been abroad, nor of nasal trouble in the pack. Briefly stated, the life history of the *linguatula* is as follows: (Neumann's Parasites, 2nd edition).

"The female *linguatula* deposits its ova in the nasal cavities of the dog, and they are expelled along with mucus. Falling upon pastures or forage—where they may retain life for several weeks—these ova, containing embryos, may be

swallowed by herbivora, when the shells are dissolved and the hooked embryos set at liberty in the intestine of the new host. The embryo bores its way through the intestine and reaches the organ in which it is to be encysted, where it is transformed into a motionless, rolled up pupa. Some time afterwards by a series of moultings the latter becomes a secondary larva, with elongated body divided into 80 or 90 segments with fine points on their posterior border, and is completely developed in six or seven months, measuring about $\frac{1}{4}$ inch. After a certain time these mature larvæ begin to move by means of their hooks and fine spines, and fall into the pleural or peritoneal cavity of their host, where many die, others may encyst themselves at some other point. If the viscera of the herbivorous host are swallowed by a dog these agamous larvæ reach the nasal cavities of their new host either by the nostrils, the guttural openings, or in ascending from the pharynx or œsophagus. Once the nasal cavities are reached, towards the third week in one moulting the larvæ lose their numerous spicules and have a smooth skin. At the same time the genital organs are completely developed, and they may copulate about the end of the 6th or 7th week, after which the females—which are much larger than the males at maturity—soon assume their definite size. Ovulation begins towards the sixth month of the parasite's nasal existence, and is continued for an undetermined period."

From the foregoing, it appears that the otter hound must have been affected about six months at least as the female parasite present was fully matured. No male parasite was discovered.

The condition of the middle ear, which was the cause that led to the hound's destruction, points to the danger of neglecting canker of the ear, and the necessity for proper treatment in the early stages.

H. TUDOR HUGHES, M.R.C.V.S., B.Sc.

"MILK FEVER"—SUGGESTION FOR PREVENTION.

We are from time to time reminded that one of the chief desires of the Editor of *The Record* is that the active members of our calling shall report, through its columns, results of actual experiences, so that by comparison something of practical utility may be added to our knowledge of the mysterious laws which regulate or govern Nature's operations as affecting the animals under our care. For many years past it has seemed strange to me that the simple method of management to prevent an attack of "milk fever," now so well put before us by Mr. Blackwell, has escaped the notice of our teachers and of those who have contributed to our literature on the subject, since my own experience is entirely in accord, viz., that if a cow is not milked before calving, or for 48 hours afterwards, there is *very little* probability of her developing "milk fever." Many years ago my attention was attracted to the fact of a client with a large herd of dairy cattle never having a case of milk fever, and I

found that he always adopted this system, and, when practicable, preferred the cows to calve in the field. Further inquiry and experience since entirely confirms the soundness of this course, and I cannot call to mind an instance of failure.

Popular works advise an opposite policy. The favourite farmer's book, "Clater's Cattle Doctor," recommends "the udder to be drawn regularly as soon as the milk appears." A more up-to-date work advises "milk cow a fortnight before calving, earlier if milk can be drawn, and empty bag twice daily." (Finlay Dun).

I hope other practitioners may be induced to give their opinion of the efficacy, or otherwise, of Mr. Blackwell's suggestion. The fixing of such a physiological fact is more useful in establishing the confidence of a client than many of the so often reported "discoveries" of those anti (something) serum, which upon trial land ourselves in difficulties and our patients in disaster.

THOS. A. HUBAND, F.R.C.V.S.

Kingsdown, Sevenoaks.

THE OPERATION FOR THE RELIEF OF ROARING.

Some time ago, with reference to the operation for the relief of roaring, I suggested, in addition to stripping the ventricle, the removal of a piece of mucous membrane from the outer aspect of the arytenoid of the affected side of the larynx.

Since then I have been afforded an opportunity of carrying out the suggestion on some confirmed roarers, and the result of the operation on two of them, ten weeks afterwards, can now be reported.

Both horses made a distinct noise on the slightest exertion, and grunted badly. Now one of them makes no noise, and the other is very much improved. Both horses were useless before the operation, but they have been returned to work and are now being used as troopers. But to my mind the most remarkable result is that neither horse can now be made to grunt either by means of the stick or by exercising him on three legs, one fore leg being fixed up, Rarey fashion.

I had the advantage of hearing the horses before and after the operation.

J. J. O'CONNOR, M.R.C.V.S.

Royal Veterinary College, Dublin.

A PECULIAR CASE.

Perhaps the following peculiar case may be of interest to readers of *The Record*.

The subject was an aged shorthorn cow, due to calve in a week.

The first symptom that appeared was lameness of the right fore-foot. Within an hour of the lameness appearing, an emphysematous swelling had appeared up the leg as far as the withers, and in a very short time this swelling had extended along the back as far as the lumbar region. The animal showed great depression, was off food, the

pulse was increased in frequency but was strong, the temperature raised two degrees.

On first being told of the symptoms, I diagnosed black quarter, but the owner told me that the same animal had suffered from a similar complaint two years ago, and that he had cured her by scarifying the skin and rubbing into the incisions a mixture composed of crushed garlic and gunpowder. I also gathered from him that several cattle in the same neighbourhood had suffered from a similar complaint, many of which did not respond to the above treatment, and succumbed within thirty-six hours.

On hearing this account, my diagnosis of black quarter seemed to be wrong, and I proceeded with the following treatment: I scarified the skin over the swelling and on entering the subcutis I found it contained a colourless frothy serum, very much resembling that seen in black quarter, but it was devoid of odour. Into these incisions I rubbed pure carbolic acid, and gave the cow a stimulant draught.

Within eight hours the swellings had disappeared and the animal seemed in normal health, and has remained so since, it being now three days since I was called in.

I am at a total loss to know what was the nature or cause of condition. I might have stated that nowhere on the animal's body could I find a wound. I should very much like to know if any practitioner could explain the nature of the disease, or would give their experience of such cases if they have met with any.

L. C. MAGUIRE, M.R.C.V.S.

Granard.

ARE REGISTERED EXISTING VETERINARY PRACTITIONERS VETERINARY SURGEONS?

At the meeting of the Southern Counties Veterinary Society, held on June 26th last, some of those present in speaking on the "Tuberculosis Order of 1913" seemed grieved that "existing veterinary practitioners" should be appointed veterinary inspectors under the Order.

I do not know if their appointment is legal, as they are neither "veterinary surgeons" nor on the "Register of Veterinary Surgeons."

In Section 3 of the Veterinary Surgeons Act, 1881, it definitely states that "The Register of Members of the Royal College of Veterinary Surgeons shall be styled the Register of Veterinary Surgeons."

In Section 15, Clause 1, of the same Act it is enacted that those who had "practised veterinary surgery" five years before the passing of that Act, and were not on the "Register of Veterinary Surgeons" were entitled to be placed on a separate Register under the heading of "Existing Practitioners."

In Section 17, Clause 1, it says those who are for the time being on the Register of Veterinary Surgeons or held the veterinary certificate of the H. and A.S.S. at the time of the passing of the Act,

1881, were entitled to use any name, title, etc., stating they were veterinary surgeons, etc.; and Clause 2 of the same section gave them power to recover fees in a Court of Law.

According to the Charter of 1814, Members of the Royal College of Veterinary Surgeons are *exclusively* entitled to "be individually known and distinguished by the name or title of veterinary surgeons," and the veterinary art as practised by the Members of the Royal College of Veterinary Surgeons is to be "deemed and taken to be and recognised as a profession."

Nothing in the Acts and Charters give the "Existing Veterinary Practitioners" on the separate Register, known as the "Register of Existing Practitioners," the right to term themselves veterinary surgeons, members of the veterinary profession, or to recover fees in a Court of Law.

Not being on the Register of Veterinary Surgeons and therefore not having the privileges or power of veterinary surgeons, they have not the responsibilities and are not subject to the disciplinary bye-laws of the Royal College of Veterinary Surgeons as are the members of the veterinary profession. In fact the R.C.V.S. has no control over them.

SCRUTATOR.

ABSTRACTS FROM FOREIGN JOURNALS.

AN ANGIO-FIBROMA OF THE CHORION IN A BITCH.

Sparapani records (*Il Nuovo Ercolani*) the case of a King Charles bitch, which aborted with very violent labour pains. The foetus expelled with its adnexa was about five weeks old. The foetal envelopes weighed altogether 75 grammes (nearly 2 2/3rd oz.), and contained a larger quantity of amniotic fluid than was normal. Externally, upon the chorion, about 4/5ths of an inch from the right edge of the placental ring, was a kidney-shaped, reddish-yellow, lobulated tumour the size of a walnut and weighing 38 grammes (nearly 1 1/3 oz.)

The upper free surface of this tumour was turned towards the wall of the uterus, and showed many furrows of varying depth, while the lower surface was only loosely connected with the chorion, and could easily be detached from it. The tumour was soft in consistence; and its sectional surface showed two distinct zones, a cortical and a central. Of these the cortical zone was rather the darker and firmer, while the central zone was lighter in colour and softer. About the periphery, and in places also at the centre, were openings of bloodvessels which were visible to the naked eye.

Microscopically, the most striking feature of the tumour was the great number of small vessels, for the most part only coated with an endothelial layer, and altogether giving the tissue a sieve-like appearance. In the peripheral part of the tumour there were also larger vessels resembling small arteries or veins, with muscular and connective tissue in their walls, and capillaries grouped in a radiating arrangement around them. The ground substance of the tumour consisted of connective

tissue elements in different stages of development—large roundish or spindle-shaped cells, and numerous fibrillæ. The fibrillæ were especially prominent in the centre of the tumour, where there were also some groups of plain muscular fibres.

Sparapani thinks that in consequence of its position between the chorion and the uterine wall, the tumour had probably acted as a foreign body, and successively induced hydramnion and abortion. —(*Münchener Tier. Woch.*)

W. R. C.

THE VETERINARY PROFESSION AND THE ANIMALS ANÆSTHETICS BILL.*

By FREDERICK HOBDAY, F.R.C.V.S., F.R.S.E.,
Kensington, W.

There is much more than appears on the surface in the subject of the compulsory use, by law, of anæsthetics in operations upon animals, and I am bringing it before you to-night in order that the expression of opinion may be obtained from members of the Central Association as representing the largest, and one of the most influential bodies of practising veterinary surgeons in the British Empire. It is a subject of such vital importance to us, that if passed, this Bill will have a revolutionary effect in more ways than one, and I cannot understand the lay promoters of the Bill attempting such a vast and important subject without first seeking advice from a large number of members of the profession who are in daily active practice, and who are in a position to point out the practical difficulties which confront a man who is told that he *must* use such-and-such an anæsthetic when performing such-and-such an operation without being allowed to use any discretion whatever.

As at first put forward, the clauses of the Bill were so obviously absurd and unworkable that it was quite evident that no veterinary surgeon of practical experience could ever have been consulted, and had it become law it would have inflicted cruel hardships upon animal, operator, and owner alike. In fact it savoured a little, unintentionally, I am sure, of being an insult to the humanity and intelligence of the members of the veterinary profession.

Gentlemen, we of the veterinary profession do not pose as sentimental faddists, but we give way to no man, and to no body of men, in our desire to alleviate the sufferings of animals. It is our life's calling, and even if we did not do it from this point of view we should always do it from grounds of convenience, for I am sure I am echoing the views of everyone present when I say that it is much nicer to operate upon a quiet patient than upon a shrieking, groaning, and struggling one.

I am going to emphasise the statement that we are all in absolute accord in our desire to use an anæsthetic for every operation; it is when we come to the practical application of the idea that we find the difficulties arise. Animals are not human beings, their consent is not asked as to whether such-and-such an operation shall, or shall not, be performed, and the two chief reasons operations are performed upon them are those of necessity—to benefit the patients by saving or prolonging their lives, or to enable them to be of service to man, as, for example, operations such as castration, ovariotomy, etc. In each case operative interference becomes a necessity if their lives are to be spared—in the first it is obvious, for if we keep animals, whether for work or

pleasure, the responsibility of looking after their well-being is a duty which we must not shirk; and as regards the second, the operations which increase their utility for the service of man; that, too, is obvious to all practical minds without going into specific details. Granted these two points of view, the idea comes into one's mind as to the best way of getting them carried out *with safety to the patient*. Therein lies the rub! With safety to the patient—for of what benefit is it to the animal if we operate on him painlessly, but kill him in the process.

To us as veterinary surgeons, the owners and general public look to lead the way in matters pertaining to the surgery of animals, and not only do they look to us to operate humanely, but they also look to us to operate safely and to restore again to them their animals alive. The animal is not grateful if it dies under the anæsthetic, and the owner is (to put it mildly) certainly not pleased, and herein lies the sum and gist of the whole matter. Our knowledge of anæsthetics is not so complete that we can say their universal application by rule of thumb at the command of the Law is without danger to life. In fact, to put it briefly "anæsthetics are not fool-proof," neither are they in human practice. To use them we must have discretionary powers, and as it is only by the qualified and educated veterinary surgeon that such powers can ever be properly understood in their finest sense, it is only to them that such discretionary power should be granted.

We are, unluckily, a small profession, and unfortunately, too, we are a modest one, but in questions pertaining to the surgical and medical treatment of animals it behoves us to assert our right to be first, and we fail in our duty to the public, as well as to ourselves, if we do not make ourselves heard, and heard authoritatively too. We are foolish if, when we can help it, we allow ourselves to be dictated to on subjects particularly our own, and subjects to which we devote our lives and make a special study of.

Let us take the Veterinary Operations (Anæsthetics) Bill in theory and dissect out its application in actual practice. As at first drafted, no doubt it meant well but as a practicable measure it was an absurdity. For example, we were to be compelled to use chloroform for any operation mentioned in the first Schedule of the Act when the horse was the subject, and this included castration, extraction of molar teeth, trephining, and enucleation of the eyeball—in all of which such compulsion was inadvisable without discretion being left to the operator. Trephining and nucleation of the eyeball are each done as a routine measure with cocaine and adrenalin, or some other local anæsthetic, and the question of castration, put in the list merely as castration, has caused quite a lot of opposition.

At the present time thousands of horses are castrated in the standing posture, and when done by an expert, if the operation passes off without a hitch, the whole thing takes but a very few minutes, and the animal usually goes straight to his manger immediately afterwards and feeds. Whether the horse, if he could be consulted, would prefer to be thrown down and go through all the fright of this and of being chloroformed, a process averaging fifteen or twenty minutes, or whether he would prefer to be operated upon in the standing posture, and have the whole thing finished with in less than five minutes, is a matter of question.

At any rate the promoters of the Bill have recognised some difficulty here, for they have now added paragraph (b) which reads: "A horse two years old and over shall not be subjected to the operation of castration unless during the whole of the operation he is under the influence of some general anæsthetic of sufficient power to prevent him from feeling pain," whilst the paragraph

* Read at the meeting of the Central Veterinary Society, Thursday, July 3rd.

relating to bulls and pigs over six months old has been deleted altogether.

I think the cat should also be included in Paragraph 2 (a) as well as the dog, for thousands of them are operated upon every year, both for castration and ovariectomy.

The question of chloroform for the bull and pig has at present been withdrawn, wisely too, until we can find a definite and safe anaesthetic for these animals. It is not merely a question of fee, but a question also of safety, and in connection with this latter point it is interesting to note that the term "general anaesthetic" includes chloral hydrate, and in the case of the dog, morphine.

The first Schedule as it stands now includes—

Radical operation for quittor.

Operation for stripping the sole.

Radical operation for poll-evil.

Radical operation for fistulous withers.

Line firing.

The word "Radical" in front of the operations for quittor, poll-evil, and fistulous withers has given considerable latitude, although what it really means I do not quite understand, and no one will dispute that a general anaesthetic should always be used for each of them; but over the question of "line firing" I expect to hear some argument, as this covers such a diversity of things, and may include anything from the few lines passed over a curb to the space covered when doing a couple of sprained tendons.

To be compelled to use a "general" anaesthetic to fire a small curb would be an unnecessary danger to the patient, and this heading certainly requires modification.

Second Schedule. The second Schedule includes castration and ovariectomy, and when the Bill was first drafted included horses of all ages. As I said a few moments ago, it has been now modified as follows:—

"A horse two years and over shall not be subjected to the operation of castration unless during the whole of the operation he is under the influence of some general anaesthetic of sufficient power to prevent him from feeling pain."

If the standing operation is to be at all considered, then this clause will have to be reconsidered so as to give horses three or six months longer—for so many are born in February or March, and the owner prefers to wait until the weather is favourable, in April or May before castrating—so that these colts would be a month or two over the exact age, and would have in future to be chloroformed for the operation if the exact age of two years was stipulated.

The chief points which we, as veterinarians, have to think about are that if the Bill becomes law we shall be compelled to become expert anaesthetists, and we must be prepared for this. That we all desire to save our patients from pain is acknowledged, and it behoves our Colleges to see that the present-day student is well equipped with practical, as well as theoretical, knowledge upon this point.

As regards the passing of the Bill, I think that its supporters mean to go ahead and get it through, and perhaps it will here be of interest if I read an extract from a letter which I received some months ago from one of the chief promoters of the Bill.

"I drafted the Bill last year with the help of various horse owners, and local veterinary advice, rather with a view to obtaining the expression of opinion on this subject than in the hope of its passing this session. I have now drafted certain amendments which I think meet the criticisms urged in your article, and which I hope may also satisfy the opposition of agriculturists. I need hardly say that I shall be very glad to consider any further suggestions which you may care to make. I may mention that I am altering the title of the Bill to discourage the common criticism of agriculturists

that it is promoted by the veterinary profession in order to injure the unqualified operator. I need hardly say that I have no desire to suggest that the veterinary profession have not on the whole done everything in their power to ensure that operations should be performed under humane conditions. I know, however, that in many cases by going against the prejudice of farmers in the matter of anaesthetics they ensure that unqualified and less squeamish operators are called in on future occasions. You will notice that by the insertion of the word 'radical' to qualify certain operations in the first Schedule I leave the power of judging the necessity for anaesthetics to the operators themselves."

And from a second letter more recently received I extract the following:—

"I fear it will be impossible for me to take advantage of your kind invitation to attend the meeting of the Central Veterinary Society next Thursday, as I shall almost certainly not be in London. If, however, my plans were unexpectedly to change I would let you know, and perhaps you will allow me still to come. Meanwhile I had better let you know the present position of the Bill, so that you may convey any information on the subject which you think useful to the meeting."

The Bill is at present being blocked by several Nationalist Members at the instance of various Associations of farmers in Ireland, who object to what they consider to be an interference with their personal liberty. I hope, however, that with patience the difficulty may be got over, especially in view of the very encouraging resolutions which have been passed in favour of the Bill by various Agricultural Societies in Great Britain.

I am very sorry not to be able to come and meet members of the veterinary profession, so as to discuss this subject, as I should like to have had the opportunity of explaining how far it is from my purpose that the Bill should cast any imputation whatever on their anxiety to avoid any unnecessary infliction of pain on animals. The real difficulty of the present position seems to be that so long as an operation is not performed for the purposes of research, but merely for the convenience of the animal's owner, that owner is in a position to employ any unskilled person and is allowed to inflict any suffering he thinks fit upon an animal. This unchecked power in the hands of inhuman owners necessarily ties the hands of the veterinary profession. They must often feel that if when called in they insist on using an anaesthetic, the only result will be that on the next occasion the owner will have recourse to someone with less skill and less scruple.

It is no reflection on the veterinary profession to recognise that, under the existing law they are often bound to feel that it is better to yield to the owner's wish and perform an operation without an anaesthetic, rather than to encourage that owner to have recourse to an unskilled man who would inflict very much more suffering.

I should very much like to have been able to attend the meeting to explain this matter, and to pay my humble tribute to the humanity of the veterinary profession as a whole.

I quite see the force of your suggestion to provide for a certain discretion being allowed to the veterinary surgeon, where, owing to the physical conditions of the patient, an anaesthetic would be dangerous. This matter and also the suggested additions to the schedules can of course easily be dealt with in Committee."

I may say here that I had regrets expressed by two other prominent supporters of the Bill that, owing to important Parliamentary duties they were prevented from coming here this evening, and I am sure that in

all these gentlemen we have men who are good friends to our profession, men who are not bigots, and who are open to receive suggestions, and it is with a view to obtaining these suggestions that I bring the subject before you this evening.

That the Bill will go through successfully is, I think you will agree, the wish of the whole profession, but we must not be tied up. We must have proper discretion left to us, and to us alone as qualified men, as to when and what anaesthetic to employ for our patients and our operations, so long as it is an effectual one.

VETERINARY MEDICAL ASSOCIATION OF IRELAND.

A quarterly meeting was held on Wednesday evening, 28th May, in the Gresham Hotel, Dublin. The President, Mr. P. J. Howard, presided. There were present: Messrs. McKenny, Kerr, Gray, Richardson, Taylor, McCann, Dodd, Magee, Ebbitt, Norris, Holland, Purcell, Jarratt, Carr, Wilkinson, Moffett, Hamilton, Watson, Thompson, Heney, Mahony, Hare, and Profs. Craig and O'Connor.

The CHAIRMAN: As there is a large amount of business to be done perhaps some gentleman would move that the minutes of the last meeting, which have been printed and circulated, be taken as read.

Mr. WATSON: I propose that the minutes as printed and circulated be taken as read.

Mr. THOMPSON seconded the motion which was agreed to, and the Chairman then signed the minutes.

New Members. Messrs. P. A. CARROLL, Carlow, and E. W. WILSON, Virginia, were elected members of the Association, on proposition of Prof. Craig, seconded by Prof. O'Connor.

Mr. D. S. PRENTICE, Chief Inspector of the Department of Agriculture; proposed by Mr. Reavy, seconded by Mr. Holland.

Mr. B. H. MELLON, proposed by Mr. McKenny, seconded by Prof. O'Connor.

Prof. O'CONNOR said apologies had been received from Messrs. Small, Reavy, and Elkins. There was a verbal apology from Col. Moore, and Mr. Hamilton had written stating that he hoped to be present at the meeting.

Vote of Condolence. Mr. McKENNY: Since we last met you are all aware that one of the oldest and most respected members of our Association has died—Col. Steele, and I think we should send a letter of condolence to his relatives. I move that a letter be written to his daughter expressing the regret with which the members of this Association learned of the death of Col. Steele.

Mr. FINLAY KERR seconded the motion.

The CHAIRMAN: Col. Steele was a member of this Association, and I frequently saw him representing this country at meetings out of Ireland, always with the greatest possible credit to the profession in Ireland.

The proposition was passed *nem con.*

The SECRETARY read the minutes of the last Council meeting:—

A meeting was held in the Royal Veterinary College on May 2nd. There were present: Mr. J. B. Dunlop in the chair; Messrs. Wilkinson, Norris, Magee, R. H. Lambert, Watson, Reavy, and Professors Craig and O'Connor.

The minutes of the Council meeting in January were read, confirmed, and signed. Apologies for non-attendance were received from the President, Messrs. Thompson, Holland and Chambers.

It was unanimously recommended that Mr. J. B. Dunlop should be nominated as co-trustee with Mr. McKenny, in the room of Mr. Hedley, deceased.

The following candidates were proposed for membership: Messrs. E. Wilson, Virginia, and P. A. Carroll, Carlow, proposed by Prof. Craig and seconded by Prof. O'Connor; D. Prentice, D.A.T.I., proposed by Mr. Holland, seconded by Mr. Reavy; B. H. Mellon, D.A.T.I. proposed by Mr. McKenny, seconded by Prof. O'Connor.

It was left to the Hon. Sec. and Mr. Watson to arrange the date of the next general meeting, and resolved that Mr. Howard should be asked to read a paper.

The following accounts were passed for payment—Messrs. H. & W. Brown for reprints, 7s. 6d.; reporter for special meeting, £2 2s.; Mr. A. Watson for expenses *re* deputation to D.A.T.I., 13s. 6d.; total, £3 3s.

Mr. HENY: Mr. Chairman, I beg to offer an apology to you and to the members of the Council for not having attended on that occasion. I was detained and could not get to the meeting until too late.

Mr. CARR: Is it usual for the minutes of the Council meeting to be read and signed at a general meeting of the Association? I understood that the duty of the Council was to make recommendations to the general meeting.

The CHAIRMAN: It has been usually done in the past. The object in having them read is that if there is any objection to the work of the Council the matter may be discussed.

Mr. CARR: I understand that the duty of the Council is to send out recommendations. It would not be my place, not being a member of the Council, to object to the minutes which are merely a record of what took place at the meeting being signed.

The CHAIRMAN: Do you propose any other method or recommend a different procedure?

Mr. CARR: I only raised the point on principle.

Mr. McKENNY: Mr. Carr is, I think, perfectly right as to the duty of the Council.

The CHAIRMAN: I am the culprit, and I must plead guilty to a very slight error in signing the minutes of the Council.

The minutes were approved.

THE LATE MR. M. HEDLEY.

Mr. McKENNY: Gentlemen, at the Council meeting shortly after the death of our very great friend, Mr. Matthew Hedley, it was omitted to send a letter of condolence to his family. It is, I think, quite unnecessary for me to say anything relative to the very able manner and the kind manner in which the late Mr. M. Hedley acted towards the members of this Association, and, indeed, towards the profession. His whole heart seemed to be interested in the work of this Association, and I think it would be superfluous for me to say anything further. I propose that we send a letter of condolence to his wife.

Mr. FINLAY KERR seconded the motion.

The CHAIRMAN: I am quite sure it is unnecessary for me to add anything to what has been expressed so ably by Mr. McKenny. We all know that for years Mr. Hedley identified himself with everything that tended to benefit the profession, and our Association in particular. We regret to be sending a vote of condolence to his family. He is a loss to the profession and to the Association. The motion was passed.

BENEVOLENT FUND.

The CHAIRMAN: I think the majority of you are aware that in connection with the Victoria Veterinary Benevolent Fund a committee has been appointed for Ireland to consider and report on any cases that would be brought under notice in connection with its Benevolent Fund. At the present time there are several persons in Ireland receiving aid from this Fund, and, unfortunately, there are not perhaps as many subscribers in Ireland as there should be under the circum-

stances. It is at least one thing to the credit of what I may say is a purely English society, that for years they have been giving aid to the families of deceased veterinary surgeons in Ireland, although the Society had practically no subscribers in this country, and was receiving no help from members of the veterinary profession in Ireland. I hope the members here will consider the matter, and if they are not already subscribers that they will give earnest consideration to the advisability of joining or supporting the fund, as those who are able to afford help to-day may want it to-morrow. The report for 1912 shows "that there was an increase of 100 members for 1912." Well, I am sure some of that was the result of the meeting held here in Ireland, at which a considerable number of members of the profession became subscribers. There was an increase of £24 7s. 4d. in the amount granted in relief as compared with the previous year, and the report also gives the names of the persons in Ireland who are receiving help, some of them as much as 10s. a week from this Fund. It is unnecessary for me to go into the matter further than to appeal to you to consider this question. It is worth while to support a fund which treats our members so well. Any small subscription will be acknowledged, and I am sure they will be grateful for any help.

Professor O'CONNOR: As a member of the Committee appointed to consider cases in Ireland, I may say that it is a most deserving fund, and that there are several people, distressed members of the profession or relatives of deceased members, who are in receipt of aid from it. It is really necessary that something should be done to help them. I think every one should become a subscriber. I frequently have letters from Mr. Shipley, Secretary to the Fund, telling me how much good it is doing, and how many people there are still in need of assistance. About £52 a year is spent in Ireland in helping the relatives of deceased members of the profession, and therefore it is necessary that the members of the profession in this country should do all in their power to help the Fund.

Mr. HENRY: Mr. President, allow me to say that this matter should be taken up heartily by our Association. For years there was hardly a subscriber in Ireland to the Fund which has helped the families of Irish practitioners, and I am sorry to say that there are members of our Association here present to-night who have not subscribed to the Fund. I am sure they would never miss the small annual subscription. I consider that the charity so deserving that I intend to double my subscription this year. (Hear, hear.) I say that the members of this Association have not supported this fund in the past, and as it is a work that they should support I appeal to them now to take up the matter. There are very few of us who could not afford a subscription of 10s. 6d., and as has been said already, those who are able to give help to-day may want it to-morrow. I think that perhaps the best way to help would be to ask one member in each county to make himself responsible for the collection of a subscription from each practising member in that county, and get at least 10s. 6d. from them towards the work of the Society. Since the meeting held in Dublin I feel that we in Ireland have not done our share, and it is for us to show that we are worthy of the confidence placed in us, and the support given to the widows and dependents of members of our profession, and to do something to help this institution which has done so much for us (Hear, hear.)

REPORT OF DEPUTATION TO D.A.T.I. RE ROYAL VETERINARY COLLEGE OF IRELAND.

On the 22nd April Mr. T. P. Gill, accompanied by Professor Campbell, met the deputation at 4 Upper Merrion Street. The members of the deputation were

Messrs. P. J. Howard, James McKenny, P. D. Reavy, L. M. Magee, J. A. Thompson, J. H. Carr, J. Holland, and A. Watson. Mr. D. S. Prentice, Chief Veterinary Inspector, attended in his official capacity on Mr. T. P. Gill.

Mr. Howard introduced the deputation, and dealt with the following subjects:—

1. The position of private practitioners, and the question of the staff of the College entering into competition by practising, and to obviate this to urge that the entire staff of professors in the College be retained as whole-time officers, and that their position be pensionable.
2. Veterinary dispensaries and the question of their extension.
3. To urge the maintenance of the uniportal system of entrance to the profession as at present exists.
4. The standard of education and curriculum at the College for private practitioners, and also its relation to appointments in the Army, the Department of Agriculture and Technical Instruction for Ireland, the Colonies, etc., etc.
5. The students in the College, and the question of State scholarships.
6. That the pathological and bacteriological laboratories be available to practitioners for opinion and advice.
7. Direct representation of the profession on the Advisory Committee.

Some free discussion of the subjects took place, and Mr. Gill assured the deputation that they would not admit of the College staff coming out to interfere with the functions of private practitioners unnecessarily, and also told us the Department frequently refused their sanction to the members of the present staff appearing in cases of litigation, and they would treat the College staff on the same lines.

Mr. T. P. Gill could not undertake to take any action as to the uniportal system, and suggested that the matter was one for the profession itself. He promised to give direct representation on the Advisory Committee.

The statements of the Secretary of the Department were highly satisfactory as to the intense interest they were taking in the profession, and also the broad comprehensive lines upon which they purposed working the College. The staff, he promised, would be treated liberally, and the literature and practice of the profession would receive unremitting attention.

Having thanked Mr. Gill and Prof. Campbell for their kind reception and encouraging remarks the deputation withdrew.

A. WATSON, hon. sec. to Deputation.

The CHAIRMAN: Gentlemen, you have heard this report of the work done by the deputation which was appointed at a general meeting representative of the profession in Ireland. Mr. Watson has told you what was done by the deputation. It is at least pleasing that the deputation was received very cordially by Mr. Gill and the representatives of the Department and that our recommendations in general were approved by the Department and the Department undertook to satisfy us in every possible manner. I don't think it is necessary to go into more detail, as Mr. Watson's report shows that the result of the visit to the Department was very satisfactory from our point of view.

Mr. MOFFETT: Have you a more detailed account, Mr. President?

The CHAIRMAN: I have merely the heads of the subjects discussed, and I have a few notes of the actual words I used in putting some of the suggestions before the heads of the Department. Mr. Watson's report, however, covers the whole ground.

Mr. MAGEE: There was a reporter present at the interview, and the Department have a note of all that occurred. I suppose if anyone wanted the report and asked the Department for it they would get it.

The CHAIRMAN: I don't know about that.

Mr. HOLLAND: As one who was present I think Mr. Watson has described very lucidly what took place on the occasion, and deserves great credit for the manner in which he has presented the report.

Mr. MOFFETT: Mr. Chairman, have you fuller details? I think the meeting should be put in possession of the full facts.

The CHAIRMAN: If it is the wish of the meeting I will give what facts I have. Mr. Russell was asked to receive a deputation, but he replied that he could not meet it until Whitsuntide which was several weeks away. That would have been too late, so we got Mr. Gill to receive a deputation representing the profession generally, and we put our view before him regarding the taking over of the College. The deputation met half-an-hour before going to the Department, and we had a discussion amongst ourselves with reference to certain matters that should be put forward for consideration. First of all we put, of course, the question of representation: that the deputation as coming from this Association considered that the profession should be adequately represented on the governing body of the College. We expressed approval of the taking over of the College by the Department, and we congratulated them on being the first body in the United Kingdom to establish a State-aided College. Then we thanked the Secretary, Mr. T. P. Gill, for having, at great personal inconvenience, received the deputation. We asked that the College be devoted to the turning out of highly trained students, and that the veterinary staff be whole time officers and that they should not be allowed to take private practice. We hoped that they would faithfully adhere to the arrangement by which the College was not to become a practising body and so secure the co-operation of the profession, and that the staff should not be encouraged to give evidence in cases of litigation.

You may remember that one of the grievances of long standing was that in the Veterinary College we had practically no say at all. Now we hope—at least, the Department have promised that we will have adequate representation in future, and that it will now be our own right to nominate members of our own on the Advisory Council.

There was the question of co-operation and encouragement of such co-operation by giving free treatment and keep to cases of poor people sent forward by private practitioners; and that special terms be given for special cases; and that the laboratory be at the disposal of the veterinary profession for opinion and advice.

The Department should further encourage the local practitioners by giving them some of the work at present done by special men from the Department.

That the College should not be available for study for other than the diplomates of the R.C.V.S.

That the staff and working of the Veterinary College should be distinct from the administrative branch of the Veterinary Department, on which the success of the live stock industry of the country so much depends.

All our suggestions were favourably received, and I think we may feel satisfied that things will work out to the best advantage.

Mr. McKENNY: As one of the deputation that waited on the Secretary of the Department of Agriculture and Technical Instruction for Ireland (Mr. Gill), I may say that we considered the interview most satisfactory, but, although Mr. Watson, under the circumstances he has told you of, has given an excellent report of it, I consider that our President, who has a verbatim written statement of it, should give it to you for publication;

indeed, so pleased was I with the promises made by Mr. Gill, and all he said relative to the manner in which the College would be managed, that I said to him at the meeting that what he had said should be written in letters of gold.

Mr. NORRIS: I propose that both reports be incorporated in the minutes.

Mr. MOFFETT: I think the President's is the only one which need be embodied in the minutes.

The CHAIRMAN: I daresay Mr. Watson's report gives all the information that is necessary, and his report can be included.

PRESIDENTIAL.

The PRESIDENT: In connection with the deputation, several members put themselves very much about to be present, and I think they did a good day's work for the profession when they went on that deputation. It is usual at this meeting to have a Presidential address, but on this occasion I shall not trespass on your time with any such thing, because matters of great importance are to be considered. I take this opportunity of thanking you for again electing me President, an honour which I esteem very highly. I only hope that we shall be able to look back to a good year's work. The time we are passing through, 1912-13, will always mark a very important period in the history of our Association and the profession here in Ireland. Last year we had that terrible outbreak of foot-and-mouth disease in this country, and it is at least creditable to the veterinary profession in Ireland that they were equal to the occasion. Many country practitioners must have been called upon to report on cases which was sent for official report as cases of foot-and-mouth disease. I think there is not one single case on record in which the diagnosis was not right. That, I think, is a credit to the country practitioners. The year 1913 marks a very important period, inasmuch as we now have considered the question of taking over of the Veterinary College of Ireland by the Department of Agriculture. That will lead to very great changes in connection with the College. Perhaps one of the greatest will be that our profession will have something to say in the guidance of the College. A long standing grievance has been removed, and it is to be hoped that the gentlemen nominated as our representatives will attend when we ask them, and do their part in making the working of the College a success. I won't further trouble you than to say that the Association deserves all the help you can give it, for it is the means by which you can always make sure of remedying grievances and removing some of the disabilities under which we have to work.

THE TUBERCULOSIS ORDER.

The next subject for consideration is the new Tuberculosis Order. It has been put in force a month ago in England, and the profession there have taken steps to see that the working of the Order will remain entirely in the hands of the profession in England. I foresee that in this country we may have difficulties with the local authorities in the way of remuneration. Of course there is a different state of affairs in Ireland to that which prevails in England. You have districts in which there are inspectors under the Contagious Diseases of Animals Act for each district. It is a very moot question whether the salary received as Inspector under that Act may not render a man liable to take over any work under that Act. Personally, I think this is a matter which the Association will have to consider in detail, because it will be vital to the interests of the profession. If you have one set of regulations in one country and a different set in another it would be far from satisfactory. I think we ought to approach the Department of Agriculture and ask them to recommend

a scale of fees for work under the new Order to each local authority. We all know that there are some County Councils which are not inclined to treat their officers well in the matter of remuneration. If we could get a uniform scale adopted, it would be a step in the right direction, and would be better for the community as well as for the profession. It would certainly be far better than if each member were left to make the best bargain he could with the local authority. Mr. Watson, will you put the matter before the meeting for consideration?

MR. WATSON: I have got rather tired speaking about this Order, for I had four or five hours of it to-day at the Department. There was a question I asked about Article 2 of the Order

Notice of Disease.

2—(1.) Every person having in his possession or under his charge

(i) any cow which is, or appears to be, suffering from tuberculosis of the udder, indurated udder, or other chronic disease of the udder; or

(ii) any bovine animal which is, or appears to be, suffering from tuberculosis with emaciation shall without avoidable delay give information of the fact to a constable of the police force for the area within the animal is, and the constable shall transmit the information

(a) to the Local Authority, who, if not themselves the Sanitary Authority, shall inform that Authority; and

(b) to the Department.

(2) The person in possession or having charge of the animal shall forthwith take such steps as are necessary to secure compliance with Article 9 (*Precautions to be adopted with respect to Milk, etc*) and Article 10 (*Detention and Isolation of Suspected Animals*).

The question I asked the officer at the Department was this: Supposing an owner of a beast with induration of the udder, or some chronic disease of the udder, has had a professional opinion, and that the tuberculin test proved that the condition of the udder is not tubercular, must the owner report the case? and the answer I got was, "Yes, all diseases of the udder must be reported."

I further postulated that if a prosecution were instituted against such a person for not reporting, we would not get a verdict, because the magistrate would likely hold that the intention of the Order was to get at tuberculosis of the udder, and the defendant had got the highest skilled opinion, and this opinion was founded on the best tests known to the profession, and had proved it was not a case of tuberculosis.

The conditions for applying the tuberculin test was also dealt with at the deputation to-day. It was pointed out that any owner who did not consent to the tuberculin test being applied was brought to his senses by putting the animal under restrictions, and keeping her under restrictions until the owner consented to have the test applied. We had also a long discussion upon Article 7:

Post-mortem Examination of Slaughtered Animals.

7.—(1.) In the case of every animal slaughtered under this Order, the Local Authority shall cause the carcass, at the time of slaughter or as soon as practicable thereafter, to be examined by a Veterinary Inspector of the Local Authority, or (if so required by the owner or person in charge of the animal before it is slaughtered) by some other veterinary surgeon, who, failing agreement between the Local Authority and such owner or person, shall be nominated by the Department but paid by the Local Authority.

(2.) The Veterinary Inspector or other veterinary surgeon shall at the conclusion of his examination give

to the Local Authority and to the owner of the animal a certificate of the result of the examination in the Form set forth in the First Schedule hereto or to the like effect, and shall send a copy thereof to the Department.

On first reading, that paragraph conveys the idea that the Veterinary Inspector makes the examination, and then if the owner is dissatisfied he calls in another veterinary surgeon to make an examination, and if they disagree an arbitrator would be appointed by the Department. This is not the meaning of this clause, but it meant the owner is not satisfied with the local authority's veterinary inspector and won't have him. He then names some veterinary surgeon, and submits his name to the Department, and if they approve he proceeds to work. If, however, they don't approve, and the owner fails to nominate a person worthy of their approval, then they nominate a veterinary surgeon themselves. At present the section is ambiguous and embarrassing.

We next considered Sub-section 4, Section 8.

(4.) For the purposes of this Order an animal slaughtered under this Order shall be deemed to have suffered from advanced tuberculosis

(a) When there is miliary tuberculosis of both lungs;

(b) when tuberculous lesions are present on the pleura and peritoneum;

(c) when tuberculous lesions are present in the muscular system, or in the lymphatic glands embedded in or between the muscles; or

(d) when the carcass is emaciated and tuberculous lesions are present.

A question was asked in reference to chronic tuberculosis. I argued that they might have all these lesions or none of them, and still be bad cases. The section did not mention the viscera and their lymphatics.

Another question which was raised was in reference to Article 9, dealing with the question of inspected milk. "If the animal is reported a suspect for tuberculosis of the udder, the milk shall not be used while the examination of the milk is going on, or which the animal is under restrictions. The milk shall not be used for man or for the lower animals until it has been boiled or sterilised, and the utensils in which the milk is collected shall also be sterilised." I pointed out the great difficulty in getting that carried out. I always serve notice in such cases that the milk is not to be used even for the lower animals without being sterilised. We all know how the owner regards such restrictions, and that he does not fully appreciate the danger of using such milk when it is a question of £ s. d. If we serve notice, when we turn our backs they go on in the same way as if no notice had been served. In fact, to make it effective you would want to have an inspector on the premises from the time the milk is drawn until it has been disposed of. You have no power to slaughter unless the owner agrees, or the Department steps in and says "it must be slaughtered."

Another matter discussed was the detention and isolation of animals. Of course detention and isolation of animals is ordered only when the milk is being tested. Then with reference to the examination of the milk. You may find no tubercle bacilli the first time, and may perhaps require four or five samples before you get the necessary result for either the removal of the Detention Order or the issuing of an Order for the slaughtering of the animal.

Then there is the moving of the animal from one district to another. I put an animal under restrictions for the examination of milk; I don't get the results which would justify my keeping on the restrictions, and they are removed. The animal goes to another district. The veterinary inspector takes a sample of the milk, but he is luckier than the man in the previous district and gets it at the psychological moment—when the bacilli are present, and the reflection is on the man

in the first district. If a man has to take four or five samples from every cow in a large district I don't think he would live long, his duties would be so multifarious. The enforcing of this Article is of considerable importance, and it is quite possible that it may lead to considerable friction.

Veterinary inspectors in cities and large towns where large markets and fairs are held, have very important duties thrown on them in Article 11.

11.—(1.) A Veterinary Inspector or a Local Authority may by notice served on the owner or person in charge of a bovine animal exposed in a market, fairground, or saleyard which appears to him to be

(i) suffering from tuberculosis of the udder, indurated udder, or other chronic disease of the udder; or
(ii) suffering from tuberculosis with emaciation, require the animal to be removed from the market, fairground, or saleyard to the premises from which it was brought thereto, or if the owner or person in charge so desires, to any other suitable premises, to be specified in the notice, and thereupon the animal shall forthwith be moved by the owner or person in charge to those premises for the purpose of examination under the foregoing provisions of this Order.

(2.) Where the premises to which the animal is required under this Article to be moved are not in the same District as the market, fairground, or saleyard, the Inspector serving the notice shall forthwith send a copy of the notice to the Local Authority of the District in which the first-mentioned premises are situate.

I asked the Chief Inspector, did this imply that we were to turn animals out of the market and send them back to the district from where they came, merely acting on suspicion, and the reply was "Yes, act on clinical manifestations." I pointed out that it would be a great hardship on the owner if, after the animal had been sent back many miles by train at a considerable cost, it was found not to be affected with tuberculosis. If before paragraph (11) there were placed the first few lines of paragraph (12) it would help to strengthen the hands of the local authorities and clear the atmosphere considerably. I suggested that that should be done, but the Department would not harken to me.

Mr. HAMILTON: Is it punishable to take suspects or ones under detention to the market?

Mr. WATSON: Yes. There was just one other point that I touched upon, and that was in reference to Article 4, which states:

4.—(1) Where a Local Authority, from information received under the preceding Articles or otherwise, have reasonable ground for supposing that on any premises in their District there is a cow which is suffering from chronic disease of the udder or giving tuberculous milk, or a bovine animal which is suffering from tuberculosis with emaciation, the Local Authority shall with all practicable speed cause such veterinary examination of the bovine animals on such premises to be made by a Veterinary Inspector as in the opinion of the Local Authority is necessary to ascertain whether any cow thereon is suffering from tuberculosis of the udder or giving tuberculous milk, or whether any bovine animal thereon is suffering from tuberculosis with emaciation, and for that purpose the inspector may, with the previous consent in writing of the owner of the animal or of his agent, but not otherwise, apply the tuberculin test to any cow which the Inspector suspects of suffering from tuberculosis of the udder, or of giving tuberculous milk, or to any bovine animal which he suspects of suffering from tuberculosis with emaciation.

Now, in dealing with local authorities you will have difficulties. One local authority will instruct their officer to make a visual inspection. Another will urge the fullest use of the tuberculin test, and therefore you

will have no uniformity of action on the part of the various local authorities.

These are the main points of the Order. Perhaps Mr. Hamilton, who is well versed in the Order will be able to give us some others.

Mr. HAMILTON: In the first place the procedure is different from that of other diseases under the Diseases of Animals Acts. It is complicated, tedious, and responsible, it will generally be necessary to either examine the milk, the excretions, apply the tuberculin test, and in cases to go over all of them. Then in the case of disease, another visit is absolutely necessary to make the post-mortem. Thus the simplest case entails two visits, and the average will require three or more. This entails loss of time and expense, the amount depending to a great extent upon the distance the subject is located from your residence. I think this is a subject for very careful consideration, and we ought to at least suggest a scale of fees for each visit, so much for a first, a second visit, testing, etc., and for post-mortem examinations, or a suitable increase in the salaries of inspectors; and in either event I would insist on getting travelling expenses or allowances of say 1/- per mile for the single journey.

I am not proposing anything, but mention those matters for the consideration of this meeting. Such a scale approved by this Society would be of material assistance to inspectors when applying to their respective local authorities for remuneration for their services.

Mr. EBBITT: Am I to take it from the reply of the Chief Inspector to Mr. Watson, that induration of the udder was invariably tubercular?

Mr. WATSON: No, no.

Mr. EBBITT: Induration was supposed to give the inspector a slight idea.

Mr. WATSON: It is induration of the udder and as such must be reported.

Mr. EBBITT: After an experience of five years in the abattoirs of America, I found that induration of the udder is not always tubercular, and if an animal that is not tuberculous is slaughtered, and the people get to know of it, then you will lose the respect of the people. If there is tuberculosis you will find it in the lymphatics, the pharyngeal, pre-scapular, inguinal, and mesenteric—form sure guides not mentioned in the Order. I spent five years as a Government Inspector in America, and I was also employed by some of the largest packers to watch the Government inspectors, and I think I know something about this question. You may have indurated udders in cows and yet have no tuberculosis.

Mr. WATSON: That is my point. I think that the percentage of indurated udders that are tuberculous is very small.

The CHAIRMAN: Will you let me remind you of what I said at the outset of this discussion that I think it would be far better if you concentrated your attention not so much upon the interpretation of the Order or clauses of it, but gave more attention to the remuneration inspectors should receive for working the Order. I think we may take it that the veterinary inspector may be fairly well able to interpret the Order. If he is not able to do so already I am sure he will be after he pays a visit to the officers of the Department from whom the necessary instruction will be given, or at least after listening to their words of wisdom in reference to the Order he will come away fully prepared with all knowledge necessary to interpret the Order. What we want to consider as an Association is perhaps as interesting, and that is the question of remuneration.

Mr. TAYLOR: What are we to suppose about a case of an indurated udder and we get a reaction after applying the tuberculin test?

The CHAIRMAN: That it is a case of tuberculosis.

Mr. TAYLOR : Tuberculosis of the udder.

The CHAIRMAN : Not necessarily.

Mr. TAYLOR : If it is a case of an indurated udder and the cow reacts what is to be done ?

A MEMBER : You must prove that she has tuberculosis before you can slaughter the cow, and she must also be emaciated.

Mr. CARR : I don't altogether agree with the Chairman on this question. You have two classes of inspectors to take into consideration. I have nothing to do with the Board of Agriculture. I am independent of it altogether. I am an inspector under a local authority—a local sanitary authority, which according to the Diseases of Animals Act must be acquainted with the existence of tuberculosis. I fear that in the carrying out of this new Order you will have overlapping of duties. For instance, the report to the local authority is made under the Diseases of Animals Act, 1904.

The CHAIRMAN : The local authority now is the County Council.

Mr. CARR : For Dublin the local authority would be the County Council, and the Urban Councils of Blackrock, Dalkey, and Kingstown are the sanitary authorities to whom under the Act of 1904 the report would be made. What are we going to do in that case ?

Mr. HAMILTON : You are not going to do anything at all.

Mr. CARR : When a case is reported to the sanitary authority the inspector under it has to investigate and report. I want to convey to this meeting that you have two classes of inspectors to look after.

Prof. CRAIG : Not from the point of view of remuneration.

Mr. CARR : As regards the remuneration, the same man who carries out the inspection under the Diseases of Animals Act will largely carry out this Order ; in fact the dairy inspectors will be largely responsible for the working of the Order, for they are more in touch with the cows that it is intended should be weeded out by means of this Order. I am surprised at the way this Order has been drafted. I am informed that the local authority can order the slaughtering of an animal that has been reported by the dairy inspector and found by him to be tuberculous, and pay compensation up to £10 without asking the sanction of the Board of Agriculture.

The CHAIRMAN : We cannot allow this general kind of discussion to go on. We must get the business done.

Mr. McKENNY said as this Order can be interpreted in different ways, and Mr. Watson has clearly shown that it can, and that if we carry it out as it is we would bring our profession into disrepute; we should inform the authorities of the objectionable portions of the Order and ask that the Order be amended. Mr. Watson has also shown us the hardships that may be imposed on owners of cattle by the carrying out of this Order in its present form. For many years I have advocated that all these official orders should be drawn up in such a manner as to make them to the direct interest of the owners to co-operate in strictly carrying them out, indeed, otherwise it is unjust and unreasonable to impose penalties on the owners for carrying out orders that are framed for the welfare of the nation.

The owners who faithfully carry out the orders under the Contagious Diseases of Animals Acts should be indemnified from loss by so doing, and if they are not, it cannot be expected that they will willingly co-operate against their own interests ; and thus it can be easily imagined the manner in which the orders are carried out, and explains their failure in comparison to what they would be if they were willingly carried out with the co-operation of the owners.

We as a profession should not accept this Order without protesting if we do not consider that we can

carry out the duties allotted to us in an honourable manner becoming to the dignity of our profession. Of course those members of the profession holding appointments under the Contagious Diseases (Animals) Acts cannot be asked to throw up their appointments, and they will only be expected to carry out the Order to the best of their abilities to satisfy the authorities, be just to the owners and behave honourably towards each other ; as it seems from what Mr. Watson has explained to us that it is probable that tuberculosis bacilli may not be discoverable in the milk of a cow one day, and in a few days afterwards it can be, and as it is quite likely that two, or more, veterinary surgeons may be called on to examine the same cow at short intervals, and the results may be different, and therefore the opinions may be opposed to each other, although if the same samples were examined by all of the veterinarians they would agree. This fact should be made generally known by the veterinarians concerned.

Perhaps, when the Order is closely studied, it may not be as defective as it appears.

Mr. TAYLOR : Is it exactly the same as the English Order ?

The CHAIRMAN : I think it is.

Mr. HAMILTON : We are not asked to accept the Order.

Mr. THOMPSON : I am sure we are all deeply grateful for the explanations given by Mr. Watson and Mr. Hamilton. I think we should put all on one side and act on the advice of the President, and see if we can come to some arrangement as to the remuneration to be given to Inspectors for carrying out this Order. It would, in my opinion, be far better if we could get a uniform rate for the whole of Ireland. We know that if it is left entirely to County Councils, one will deal with it in one way and another in a very different way. We should adopt the suggestion of our President, draw up a scale of charges, submit it to the Department, and ask them to recommend it to the Council Councils for adoption as fair and reasonable. It would be far more satisfactory than leaving each inspector to make the best bargain he can with the local authority.

Mr. WATSON : In dealing with this question of increased remuneration for extra work, it should be borne in mind that the Treasury only proposes giving a grant for five years. It is to be a decreasing grant. Then at the end of the five years it may cease. If we are going to have a scale of fees for work in connection with this Order we must bear that fact in mind when fixing the charges.

Mr. THOMPSON : I don't know how the County Councils pay their inspectors in the South of Ireland, but in the North they frequently pay big fees—a fixed fee being allowed for each visit. Where it is the custom to pay a yearly salary, then I think a substantial increase should be granted to cover the extra work.

Mr. WATSON : We should take up the Order and ask the local authorities for fees for working under it, and then if they turn a deaf ear we can go to the Department and ask them to recommend a scale of fees to the local councils. Another point is with reference to a cow with an indurated udder being sent to market. A man with a cow of that kind has no business to send her to market, and if he gets a lesson by a substantial fine once he may not try it again.

Professor CRAIG : I may say I am the culprit responsible for bringing forward this subject for discussion, and for postponing the paper which our President had promised for to-night, but I hope that at the next meeting we will be favoured with that paper. I thought this Order of such very great importance to the profession that, as it comes into force next month, we should have an opportunity of considering and discussing the best methods of procedure, as well as the question of remuneration. Our President has emphasised

the necessity for dealing with the question of remuneration, but I think at the same time we should make certain that we are thoroughly conversant with the Order and its successful working. This is the first time that the State has begun to tackle the question of bovine tuberculosis, and if the Order is successfully carried out it may lead to a more complete control of the disease. It may be the beginning of great things for the profession, but this will depend to a great extent upon the capabilities shown by the veterinary inspectors and the local authorities. The cases of tuberculosis dealt with under this Order are tuberculosis with emaciation, tuberculosis of the udder, and tuberculous cows excreting tubercle bacilli in the milk. With regard to the last mentioned cases, we know that certain tuberculous cattle give tuberculous milk, although no lesions can be found in the udder. That has been shown by the experiments of the Royal Commission on Tuberculosis. The cases in which this occurs are cases of advanced tuberculosis—animals showing marked symptoms of the disease. It is not at all likely that the tubercle bacilli will be found on microscopic examination of the milk of these animals. As a rule these animals may be dealt with under the heading of tuberculosis with emaciation. The question of differential diagnosis of tuberculous udders requires careful consideration. Even after the clinical symptoms point to tuberculosis of the udder, we do not always find—after centrifugalisation of the milk from the affected quarter, and careful examination of stained films from the deposit, that tubercle bacilli are identified. If we come across other organisms in great abundance in films from milk which has been recently and properly drawn, the probability is that the disease of the udder is due to some cause other than tuberculosis. But where no organisms are found, what is to be done? No doubt one may take into account general symptoms, such as emaciation, coughing, disease of the lungs and diarrhoea, but these will only be suspicious symptoms. They will, however, give us some grounds for maintaining restrictions. At the same time no one desires to make this Order hard or unjust upon the owners. A diagnosis should be made as quickly as possible. If experimentation is resorted to, one may require to wait a month or more before a decision can be arrived at. In these cases resort may be made at once to the tuberculin test. If the animal does not react, presumably it is not a case of tuberculosis. If it does react, one may certainly conclude that it is tuberculosis, but cannot be certain whether the udder is affected unless there are local lesions. In some cases during the application of the tuberculin test, swelling and hyperæmia of tuberculous lesions take place. On that account the udder should be carefully examined at that time. The time at which tubercular mastitis is difficult to diagnose is in the early stages. In the later stages, when a large proportion of a quarter or of an udder is involved, tubercle bacilli will be easily discovered. It is possible that the number of tubercle bacilli in the milk in cases of tuberculous mastitis may be temporarily increased, as was done by the Royal Commission, in tuberculous animals without disease of the udder, by artificial means such as large doses of tuberculin.

In conclusion, I hope that the working of this Order will be kept within the profession, and that the veterinary inspectors will either make their diagnosis themselves or obtain the assistance for that purpose of one of their fellow members.

Mr. WATSON: If the inspector gives notice of the time when he intends to make the test, and if the owner doses the cow with a couple of doses of tuberculin two days before, we will get no reaction when we apply the test.

Mr. TAYLOR: Do you not think it would be better if the Association could offer some advice to men who

may be called upon to work this Order for county councils, and suggest to them the fees or remuneration they should seek.

Mr. HAMILTON: I think it would strengthen the hands of the local veterinarian, and also the position of the Veterinary Medical Associations. It would be better than having each man to make the best bargain he can with his local authority.

Mr. WATSON: We should make a common demand.

Mr. CARR: I am an inspector under the Local Government Board, and in the carrying out of this Order I expect trouble. The Department of Agriculture consider that they are the authority—the sanitary authority as defined in the Order we are considering, and it is the officers appointed by the sanitary authority who have the carrying out of the Infectious Diseases of Animals Act. For instance, in Dublin, Belfast, Cork, and other large cities, there is what is called the Superintendent Medical Officer of Health, and in the country districts and small towns there are the dispensary doctors, and similarly in regard to this Order you will have clashing of authorities. The sanitary authority may say our inspectors are inspectors under the Public Health Act. They should carry out the Order; or the local authority may consider that the responsibility for the working of the Order rests with their inspector. I do not think the Department took this into consideration when drafting the Order. I hardly think they will give us a new Order, but when I see Mr. Prentice I will put him one or two straight questions on the point. I don't altogether agree with the President that this is the place to consider the question of fees. I think we should consider the course of action to be taken in regard to the Order. The inspector's duties will have to be defined more clearly before we are in a position to fix a scale. What brought me here was to get some information as to the working of the Order.

Mr. HAMILTON: You will get enlightened on all the points when you go to the Department.

Mr. CARR: When the 1910 Order was issued I was an enthusiast. One cowkeeper reported to me, and I reported the case to the Department. What do you think they did? They sent a sergeant of police to make enquiries into the case, and when the owner saw the sergeant coming into the premises he was disgusted—for I need hardly tell you that cowkeepers don't like policemen coming to their places. The man refused to give the sergeant any information, and the policeman came to me to see what was to be done in the circumstances. Methods like that are a disgrace—nothing short of it. I met Mr. Hedley shortly afterwards and told him the circumstances, and he agreed that the owner was perfectly right in refusing information to the sergeant.

Mr. WATSON: This Order will not interfere with the Sanitary Authority.

Mr. CARR: The Order says, "Nothing in this Order shall be deemed to interfere with the power of Sanitary Authorities in carrying out the provisions of the Tuberculosis Act of 1908." Under the Act the Sanitary Authority has power to order animals to be slaughtered. (A Member: That is the crux of the whole matter. It will be a case of which will get in first.)

Mr. TAYLOR: I propose that we draw up a scale of fees to be submitted to county councils.

The CHAIRMAN: I suggested to the members that the principal item for our consideration was not so much the interpretation of the Order as the adoption of some scale of fees to make it remunerative. Mr. Carr seems to think that the important matter is the interpretation of the Order. The local authority is specified in the Order as the bodies to carry out the provision, and the local authorities now are the county councils. It is under these we will have to work, and we should have some scale of fees drawn up for submission to them.

Anything the sanitary authority may do in regard to tuberculosis will be done under a different Act, and will have nothing to do with this Order. Sanitary authorities will act in cases where the milk is sold, but this Order applies to all owners of stock, whether the milk is sold or not.

Mr. WATSON: Have you any particulars as to the scale of fees in England?

The CHAIRMAN: Mr. Carr need not fear that there will be any clashing between the different authorities. As to the scale of fees, I have a copy of *The Veterinary Record* and it gives the scale fixed for submission to the County Council of Kent. It may be taken as a typical county.

Some of you have found fault with me for the somewhat sordid view that I took of this Order, and may think that a scale of fees drawn like that one sent to the Kent County Council may frighten the Irish County Councils from adopting the Order at all. The question is would it be better to have a scale of fees or an inclusive charge for each case.

Mr. HAMILTON: Say a guinea a day.

The CHAIRMAN: I think fees would be better. You might have several cases in one journey of fifty miles, or perhaps more; you might have to go that distance for only one.

Mr. TAYLOR: Well, the tuberculin test should be a guinea a case, to include examining the milk.

The CHAIRMAN: I think it would be better to adopt a scale on the lines of the Kent fees.

Mr. CARR: Under the Tuberculosis Order the County Councils have appointed pathologists for examining samples of milk.

The CHAIRMAN: That is a different matter altogether.

Mr. CARR: We are back to the same point.

Mr. EBBITT: Is tuberculin made in this country.

The CHAIRMAN: Only at the Royal College.

Mr. EBBITT: I think the Department should be advised to try and make it. It is simply ridiculous that it is not made in this country. It is after all a very simple matter.

The CHAIRMAN: We should take into consideration what ought to be done in regard to fixing fees, and get a scale if possible which may be universally applied. It would also be advisable to seek the co-operation of the Department, and ask them to remember the scale which we suggest to the county councils.

Mr. HAMILTON: I don't think there will be much good in asking the Department to do that.

The CHAIRMAN: It will be too late to try to do anything when the local authorities have drawn up their own regulations. We know how many Councils treat their own officials.

Mr. HAMILTON: You refer entirely to the question of remuneration.

The CHAIRMAN: Yes. You will remember that in connection with the erection of labourers' cottages, the Local Government Board suggested certain scales of fees should be paid to the engineers. They could now do the same for us in reference to this Order.

Mr. HOLLAND: If the Department made the suggestion that a certain scale of fees should be paid, the local authorities would probably agree to what the Department would suggest.

A MEMBER: Mr. Carr has referred to local authorities having appointed pathologists. If we fall under their hand we are done for. If you send milk to the medical officer you have got no case for asking for anything. Stand upon your own feet and don't send samples of milk to the medical officers for examinations.

Mr. McKENNY: I think we should appoint a small committee to consider the Chairman's proposals as to a scale of fees.

The CHAIRMAN: I think it would be better to have a committee to represent all the provinces.

A small committee was then appointed to consider the matter, and it was agreed that it should meet at the close of the general meeting.

The CHAIRMAN: Before we go into the assembling of this Committee is there any other business to be brought before the Association or has any member any suggestion to make.

Mr. HOLLAND: In connection with this discussion we ought to ask the Department to suggest our scale of fees to the local authorities for adoption.

The CHAIRMAN: We can lose nothing by doing that.

Mr. CARR: This Association is in the habit of giving medals. I suggest that in the future they be struck in Ireland instead of in England. I saw some struck in Ireland for the National University and they were, in my opinion, superior to those the Association got in England.

The CHAIRMAN: I am sure your suggestion will be acted upon in future.

The Sub-Committee then met, and the following scale of fees was drawn up:

- | | | |
|---|----|-----|
| 1. For clinical examination of the first animal a fee of | 10 | 6 |
| Each additional animal on the same premises | 1 | 0 |
| 2. When the premises are more than 15 miles distant a fee for the first animal of | 1 | 1 0 |
| 3. For applying the tuberculin test up to four animals | 2 | 2 0 |
| Each animal over 4 | 5 | 0 |
| 4. Post-mortem examination | 1 | 1 0 |
| 5. Microscopic examination | 10 | 6 |
| 6. Mileage at the rate of 1s. per mile one way, or railway fare. | | |

It was directed that a copy of this scale of fees should be sent to Veterinary Inspectors with a recommendation that they should place them before their local authorities and not accept lower fees. A copy also to be sent to the D.A.T.I. with a request that they will recommend their adoption to the local authorities.

Royal College of Veterinary Surgeons.

EXAMINATIONS IN LIVERPOOL.

At the recent examinations held by the Court of Examiners in the University of Liverpool on July 7th for the Written, and on July 12th and 15th for the Oral and Practical Examinations, the following gentleman passed his Final Examination and was admitted a member of the Royal College of Veterinary Surgeons:—

Mr. Charles William Elam.

The following passed his Third Examination:—

Mr. Robert Parkinson Holmes. *

The following passed their Second Examination

Mr. T. A. Dobie	Mr. P. McNamee
T. A. Elam	

The following passed their First Examination;

Mr. W. F. Aston	Mr. E. P. Shallcross
E. Golding	E. J. H. Sewell
S. Pugmire *	

Marked thus * passed with Second Class Honours.

CHAS. BLACKHURST, Secretary.

EXAMINATIONS IN GLASGOW.

At the meeting of the Board of Examiners held in Glasgow on July 7th for the Written, and on July 11th and 14th for the Oral and Practical Examinations, the following gentlemen passed their Final Examination and were registered Members of the R.C.V.S.:—

Mr. J. Scott Moncrieff, Lanark.
R. McKay Lawson, Glasgow.
Tom T. Taylor, Saltcoats.

The following passed their Third Examination:

Mr. Eric E. McLachlan Mr. Wm. Watt
J. D. Fulton

The following passed their Second Examination:

Mr. A. Campbell Mr. J. Robertson
N. A. McEwen W. Macgregor

The following passed their First Examination:—

Mr. J. S. Keane Mr. F. MacKenzie
A. Robertson D. Gillmor
D. E. Orr W. R. Smith
J. M. Gray

Mr. ARCH. BAIRD, M.R.C.V.S.
Local Secretary to the Board of Examiners.

The Tubercle Bacillus.

A report on the results of a chemical investigation undertaken by Dr. Arthur Harden (assisted by Mr. S. G. Walpole) at the request of the Royal Commission on Human and Bovine Tuberculosis is published as Appendix Vol. VI. of the Final Report of the Commission [Cd 6904].

The object of the investigation was to ascertain whether it was possible by chemical means to differentiate between tubercle bacilli of the human and bovine types. The report gives a systematic quantitative comparison of the action of the two types, the principal conclusion from which is that no definite physiological difference has been detected between tubercle bacilli of different origins. It is further concluded that such differences as exist between the amounts of action exerted on glycerol beef broth by different cultures are probably to be attributed to differences between the weights of organism formed, the times of incubation, and individual characteristics of the strains. When B. Tuberculosis is cultivated on glycerol broth, the proteins of the broth undergo hydrolysis to a considerable extent. Glycerol is partially removed by oxidation. There is no evidence that consumption of glycerol is directly related either to weight of culture obtained or to change in acidity. The initial fall in the acidity of the medium is largely due to the removal of the acids soluble in ether. Further important factors in producing change in acidity are the production and removal of ammonia (free and saline) and the digestion of the proteins.—*The Times*.

Stampede of Horses at Aldershot.

The Field operations by the whole of the Aldershot Command, under the direction of Sir Douglas Haig ended on Tuesday last. About 2.30 a.m. a serious stampede took place among the horses of the Queen's Bays, who were co-operating with General Lawson's Division. The cavalry had got into bivouac within the infantry pickets, when at 2.30 they were fired upon at close quarters by a hostile patrol who had penetrated the lines. The horses stampeded instantly. Many were badly hurt and a large number escaped into the darkness, some 50 of them making straight for their stables at Aldershot, seven miles away. Six horses were so seriously injured that they were shot on the ground, several ran into a bog, from which they were extricated by Engineers, and many were badly mauled during their struggle on the picket ropes or in their subsequent gallop. Staff-Sergeant Farrier Rush and Privates Vine and Synnott were hurt in the *mêlée*, the non-commissioned officer's injuries being of a very serious nature. All three were removed at once by motor car to the Cambridge Military Hospital at Aldershot.

Personal.

WHITE.—On July 22nd, at 111 Arundel Avenue, Liverpool, the wife of James H. White, M.R.C.V.S., of a son.

TUBERCULOSIS ORDER, 1913.

Sir,

Is not the working or rather the non-working of this Act rather a farce?

Some time ago I wrote the Clerk of one of the two County Councils for which I act saying that I had a suspicious case and asking how I was to proceed. He replied stating that he was in communication with the Board of Agriculture and hoped to issue instructions shortly. However, I have heard nothing further.

To-day a client of mine informed me that one of his cows which I recently tested and which reacted was becoming emaciated; he therefore reported it to the Police who have replied stating that they have no instructions to work the Act! This puts one in an invidious position, and personally I shall not attempt to report cases in this county, as nothing is done.

In the other county for whom I act, there are three cattle markets in my district, but I have not been appointed by the county to act on their behalf, and at two of these I commonly am not present even in a private capacity, so that they have absolutely no inspection whatever, though I know that the auctioneers would prefer an inspector being present on behalf of the local authority.

This county has sent inspectors a list of fees allowed, and for the tuberculin test they allow £1 1s. for one animal plus 1/- per mile one way for one journey only, so that presuming one gets one cow to test ten miles away—one is supposed to make at least four journeys of twenty miles each, or a total of 80 miles for 31/-!!

I hope that our newly appointed Association is looking into these matters.—Yours, etc.,

July 21.

INSPECTOR.

TUBERCULOSIS ORDER, 1913—FEES.

Sir,

In reply to Mr. J. R. Robins' letter in your issue of 19th inst., re the Somerset County Council fee of 5s. for post-mortem examinations under the Tuberculosis Order, 1913, in the scale of fees sent me on my appointment as an Inspector under this Order, no special provision seems to be made for post-mortem examinations, consequently in an account which I have submitted I charged the fee allowed for anthrax exams., i.e. 10s. plus mileage.

I am glad to say the low scale of fees allowed by the Somerset County Council seems likely to be soon altered

for the better, as, thanks to the exertions of the late Mr. G. H. Elder, Taunton, ever ready to use his best efforts in the interests of the profession, the Sub-Committee of the Council have agreed to the adoption of the "National" scale of fees, and it only requires ratification by a general meeting of the Council to be held in September.

This followed on a representation from the Western Counties Veterinary Medical Association, who approached the County Councils of Devon and Cornwall in like manner.—Yours faithfully,

H. E. WHITEMORE.

Langport, Somerset. July 21.

A SUGGESTION FOR PREVENTION OF MILK FEVER.

Sir,

In the issue of *The Veterinary Record* of last week, there appears "a suggestion for prevention of milk fever" by Mr. W. E. Blackwell, viz., that the cow should not be milked for 48 hours after calving. This has been a theory in existence for a number of years amongst farmers themselves.

A client of mine who has a dairy of 70 cows had a most tenacious belief in this theory, but this summer he has had a rather rude awakening, having had no less than three cases of milk fever within a month, not one of which cows was milked by human aid! Then, again, how does Mr. Blackwell account for the numerous cases of milk fever which one gets where the cow is found down with the disease within a few hours of calving, and where the udder has never been touched?—Yours faithfully,

E. J. THORBURN.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1308.

AUGUST 2, 1913

VOL. XXVI.

THE WEEK'S MEETINGS.

The veterinary meetings which occupied the first half of this week in London were highly successful upon the whole. The one thing we could have wished for was a larger muster of members; for none of the attendances could be called more than fair, and one or two were distinctly poor. But in every case the spirit of the members made up for any deficiency in numbers.

On Monday afternoon the new Association of Veterinary Inspectors met for a comparison of experience of the Tuberculosis Order; and this proved very valuable. No doubt the proceedings will be reported; and all we need say of them now is that the discussion amply justified the existence of a Society composed wholly of veterinary inspectors, and concerned with their special work alone. Such an Association has now become a necessity to us.

On Tuesday, the "National" meetings commenced. In the morning the first place was given to Dr. Griffiths' paper on "The form of the foot of the Shire horse"—in some respects the most noteworthy paper presented this year. It consisted of original observations, which were well received by the members, and which certainly deserve following up in the future. So far as we know, Dr. Griffiths' views are quite new; and many of our members have opportunities of testing them.

The afternoon was devoted to Mr. Henry Gray's paper "Do we need a new Degree?" This produced a brisk discussion in which the bulk of the speakers inclined to the view that a Public Health Degree on the lines already projected by the Council is needed—thus answering the question in the affirmative.

The annual banquet was held that evening, and was more than successful. The attendance was just over ninety, ladies being well represented; and a not very long toast list, with some particularly good music, helped to make the function one of the most pleasant ever held by the "National."

On Wednesday morning we had Mr. Livesey's paper on "Gastric and Intestinal Disease in Dogs"—a clinician's subject, which was well discussed without revealing any great differences of opinion amongst the speakers. In the afternoon the final paper was taken, "The Milk Bill and the Tuberculosis Order," by Mr. Male. Very often the final afternoon of a "National" programme is marked by a little visible slackening in the interest of members. This one certainly was not, for Mr. Male's paper evoked a most lively and interesting discussion, which could probably have been prolonged for another hour or more had time permitted. But time did not permit—the discussion had to be ter-

minated, and then the usual votes of thanks brought this year's "National" meetings to an end.

This was the thirty-first general meeting of the "National," and the first under the new rules of affiliation. Next year the usual gathering will not be held. At the time of the International Veterinary Congress, there will be a formal meeting of the "National" for necessary business and to elect officers for another year, in accordance with the rules. Thus all members may be free to concentrate their attention upon the International Congress.

For the next two years, then, the "National" will have little to do beyond continuing, through its Council, to act as the centre of the organisation of the Societies. The place of the 1915 reunion will be chosen, and officers elected, at the brief business meeting of next year. Meanwhile, last year's officers have all been re-elected for the quiet twelve months of 1913-1914—with one addition. It has been decided to add to the working staff an assistant secretary, and Mr. W. L. Harrison has been elected. Frequenters of the "National" meetings know quite well that the selection was made on account of the capacity which Mr. Harrison has already shown as Local Secretary at more than one reunion.

ANTHRAX IN ELEPHANTS.

Before describing this outbreak, which occurred in two herds of elephants grazing in the forest two days march from Toungoo, I must attempt to give some idea of the manner in which the elephants under my supervision are kept, and then you may make allowances for any omissions in the manner of diagnosis or treatment or prophylactic measures.

In the first the animals live entirely in the jungle, the distance away from headquarters varying from two days march the nearest camp, to twelve days march the furthest camp. The animals during the off season (March, April, and May) are caught by their riders once a day and brought into camp, and again set free into the jungle to graze, after this cursory inspection by the head rider or Sinok. There is no such thing as stabling or keeping an animal under observation for any lengthened period. With these few facts in mind I will proceed with the description of the outbreak.

April 24th.—Blood smears received, taken from elephant that had died suddenly two days previously. After microscopic examination, diagnosis—Anthrax. Two more sets of blood smears coming later in the day from the same area confirmed my diagnosis. Three animals dead.

April 25th.—After forced marching, arrived here in the infected area. Another elephant "K" reported ill. On seeing the animal, in semi-darkness, find him very weak, leaning against a tree on the bank of the stream; owing to darkness I was unable to make a thorough inspection of the animal. He appeared dull, haggard look on the face, penis pendulous, eyes running, and behind the shoulder on the right side, at about the region of the lower border of the scapula, was a small well-defined swelling, which was hot and painful to the touch. The animal was lame, and disinclined to move the right foreleg. I was unable to get this animal's temperature as he was a vicious beast and would not allow it. Blood smears were taken, and I found *anthrax bacilli (few) present in the blood*, taken at seven o'clock this evening.

April 26th.—"K" reported to have died at about 2 o'clock this morning; slides taken immediately after death show large numbers of bacilli. Went to see the carcass; the animal had died in a kneeling position, the mouth, eyes, penis, and anus all showing evidences of discharges. The carcass was burnt whole, and remains covered with quicklime. The animal's tracks were followed up for two days by men with instructions to burn and disinfect all dung.

"S." Female elephant, caught this morning. Symptoms: dullness, disinclination to move, eyes running, watery discharge, excessive flow of saliva, urination frequent and large in amount, faeces normal in appearance, small amount, small well-defined swelling behind the right shoulder, hot and painful to the touch. Jaw pendulous and body temperature uneven; again unable to get temperature. The Sinok (head man) reports that when the animal was caught yesterday evening he noticed this small swelling, which did not appear to cause the animal any inconvenience. To-day the animal is decided lame. Instructions were given to chain the animal to a tree and foment this small swelling with hot water all day and every day until animal dies, or, which I did not then think possible, recovers. Slides taken, but no bacilli found. The area round about where she is tied up is being burnt over, and any faeces she may pass disinfected at once, food and water is being carried to her.

"G." Large tusker, reported with similar symptoms to "S" this morning. Slides taken, but do not show any bacilli; animal too far away to visit.

April 27th.—"G" died 3 o'clock this afternoon; slides taken show *Anthrax bacilli*. "S" still ill. Swelling on side increasing in size and extending down towards sternum. To-day all the rest of the elephants (10) that had been in contact, are moved one day's march away from this area, and each tied up to a tree in the forests, one mile apart, with two men to attend to each animal. This necessitated my shifting camp from the place where "S" is tied up, in order to daily go round the segregated animals.

April 28th.—No more cases apparent yet. "S" reported still alive, swelling increasing.

April 29th.—Inspected whole of segregated animals this morning. "M," female elephant, shows small well-defined swelling behind right

shoulder, and was slightly lame. Temperature 101. watery discharge from eyes, swelling painful and three inches in diameter; animal is tied up, and hot fomentations are to be applied continually.

April 30th.—Inspected whole of segregated animals.

"D" was in "musth," but to-day the musth glands have suddenly ceased discharging.

"M." Swelling on right side enlarged, 8 in. to 10 in. in diameter, animal apparently healthy and lively but very lame. Unable to get temperature.

"S." Swelling has burst in three places. I am unable to go and see the animal myself.

"D." Rider came in this evening reporting that a small swelling had appeared behind his right shoulder, and animal seems to be in pain. There was no sign of a swelling this morning.

May 1st.—"D." At 6.30 a.m. animal in great pain, lying down and rising continually; eyes running copiously and "musth" glands discharging freely, haggard countenance, penis pendulous, and lower jaw dropped.

"M." Still eating and lively, swelling greatly increased, extending beneath the chest and between the fore-legs, cold and slightly painful to the touch. Fomentations stopped, still lame; unable to get temperature.

"D." Twelve o'clock mid-day, rider reports death.

May 2nd.—"M." Still lively. No further outbreak.

May 3rd.—"M." Still lively and eating; swelling cold and painless, only slightly painful in the region of the original small swelling. Animal set free to graze on far side of stream. Rest of elephants moved a day's march further up stream and set free to graze as usual, as I consider the danger of a further outbreak past, after seven days strict segregation.

May 4th.—"M." Still the same; swelling being treated with tinct. iodi., and is slightly reduced. Lameness gone. Shifted camp back to the area where "S" is tied up. Still alive. Visited "S" and find swelling has burst in three places, a stinking discharge is issuing, vagina is slightly prolapsed and greatly swollen, animal very thin and miserable, men have been neglecting the animal and were severely handled in consequence (the only way to get things done out here). Sore and vagina thoroughly cleansed and disinfected, and animal properly fed and watered.

May 7th.—Returned to Toungoo.

May 26th.—Again inspected "S" and "M," both animals have quite recovered. "S" has still two unhealed sores on the lower portion of the chest wall, and as she is an old animal (about 50 years) these will take some time to heal. "M" is again fit for work. She is quite a young animal about 25 years old.

I have no doubt that these animals "S" and "M" have recovered from anthrax, although I did not find bacilli in the blood taken from them, this fact not being unusual as the bacilli are not present in the blood, to any great extent, until just before death.

In the other cases "K" died in about 60 hours

after showing the first symptoms, and six hours before death I found anthrax bacilli present in his blood.

"G" died roughly in 48 hours after the first symptoms were seen.

"D" died in less than 24 hours after showing the first symptoms. This was probably due to the animal being fairly old (45), and his resistance to disease must have been greatly reduced as he was in "mush," a period in which the elephant seems to undergo some great change.

For staining slides I used M'Fadyean's Polychrome methylene blue, John's Anthrax stain (2 per cent. Gentian violet), Leishman's, and Giemsa's stain: the two latter being modifications of Romanowski's stain.

I enclose three photographs showing our method of travelling about the jungle.

G. G. HOWARD, M.R.C.V.S., D.V.H.

Toungoo, Burma. June 13.

GOITRE (STRUMA MOLLIS) IN PUPPIES.

Some three months ago I was asked to look at a litter of eight pedigree Airedale puppies, four months old. I found all to be affected to a greater or lesser extent with goitre. The hypertrophied thyroids varied in size from an orange down to that of a golf ball. In all cases both glands were affected, though not necessarily equally so. The swellings were soft, elastic, and not nodulated.

History.—The pups had been well cared for, and were in good condition. They had plenty of fresh air and exercise, and were born and had remained in a place well above sea level.

Müller states heredity in young animals is a predisposing cause (struma congenita). I therefore examined both parents very carefully, but they were perfectly healthy, though, of course, this does not disprove the case being one of heredity.

Treatment.—Grs. 3 Potass. iod. daily in milk, water to be boiled; externally Iodine ointment to the swellings, and half a thyroid from a freshly killed sheep for each pup daily.

Result.—The swellings after five or six days started to subside, and in three weeks had disappeared, leaving the thyroids normal, and now, some nine weeks later, there is no trace of recurrence.

It is an open question whether these puppies would not have recovered spontaneously—not having had previous experience of a similar case I offer no opinion; nor am I prepared to affirm that the treatment was responsible for the rapid cure; it was simply based on the lines of the orthodox treatment for human beings. The result was certainly surprisingly satisfactory, and as I fancy the condition is not a common one, I record it.

E. S. GILLET, A.V.C.

Saharanpur, India. July 1.

A MULE MARE WITH FOAL.

A report appeared in one of the local papers (Greek) that a mule had foaled. As this is considered almost an impossibility it was received with unbelief. The Government here, being interested ordered me to proceed and examine it. I will confess I proceeded biased against the idea, as I have been in similar cases before but never found them true.

On 5th of present month I examined it and found it a genuine mule. Should say it was bay with black points, six years, 23-2½ h.h. This foal is the second: the first was a filly, last year. This one is a male. The first died after two months, the second lives. The mule was bred from a she-donkey, and the foals from her are by a jack donkey. No special marks or stripes; and in my opinion a very good type of mule. I may say that the Island is noted for its good mules and I examine many.

Circumference of knee 11 inches.

Length of metacarpal 7½ "

Circumference of sub-carpal 8 "

This is by no means the average of our donkey measurements. The mule was giving milk, and I saw the foal suckling. The foal somewhat resembles a young donkey, but bigger. I leave it to scientists to account for, but can vouch for the dam being a genuine she-mule.

I enclose a photo.

G. J. HARVEY, M.R.C.V.S.

Government Veterinary Surgeon.

Nicosia, Cyprus. July 16.

COCCIDIOSIS IN CATTLE IN NORTH DEVON.

By R. G. LINTON, M.R.C.V.S., Barnstaple.

This condition is considered distinctly rare in Great Britain, but probably many outbreaks occur, and their true cause is overlooked on this account.

As most practitioners are aware, the class of protozoons known as the coccidia is the cause of serious outbreaks of disease in rabbits, and occasionally in pheasants, turkeys, and other farm-yard poultry. An excellent account of the coccidiosis, written by H. Gray, is to be found in Hoare's System of Veterinary Medicine, 1913.

A considerable amount of doubt seems to exist as to the identity of the various species of coccidia which have been named by different authors. Doflein (*Lehrbuch der protozoen Kunde*) a well known German protozoologist, is of opinion that *Cocci tenellum*, *C. acutum*, *C. perforatum*, are one and the same parasite, affecting almost all classes of birds. *C. oviformis*, *perforans*, or *cuniculi* he considers to be a distinct variety, and further to be the same as the parasite described as *C. bovis* by many veterinary authors (Railliet, Jowett, Ostertag). These details though most important can only be decided by careful research, and the writer is here

only concerned with the clinical features of the present outbreak.

With regard to the disease in this country the only mention of its occurrence I have been able to find is by Gair, of Cononbridge, Ross-shire (*Journal of Comparative Path. and Therap.*, vol. xi., p. 171 *et seq.*)

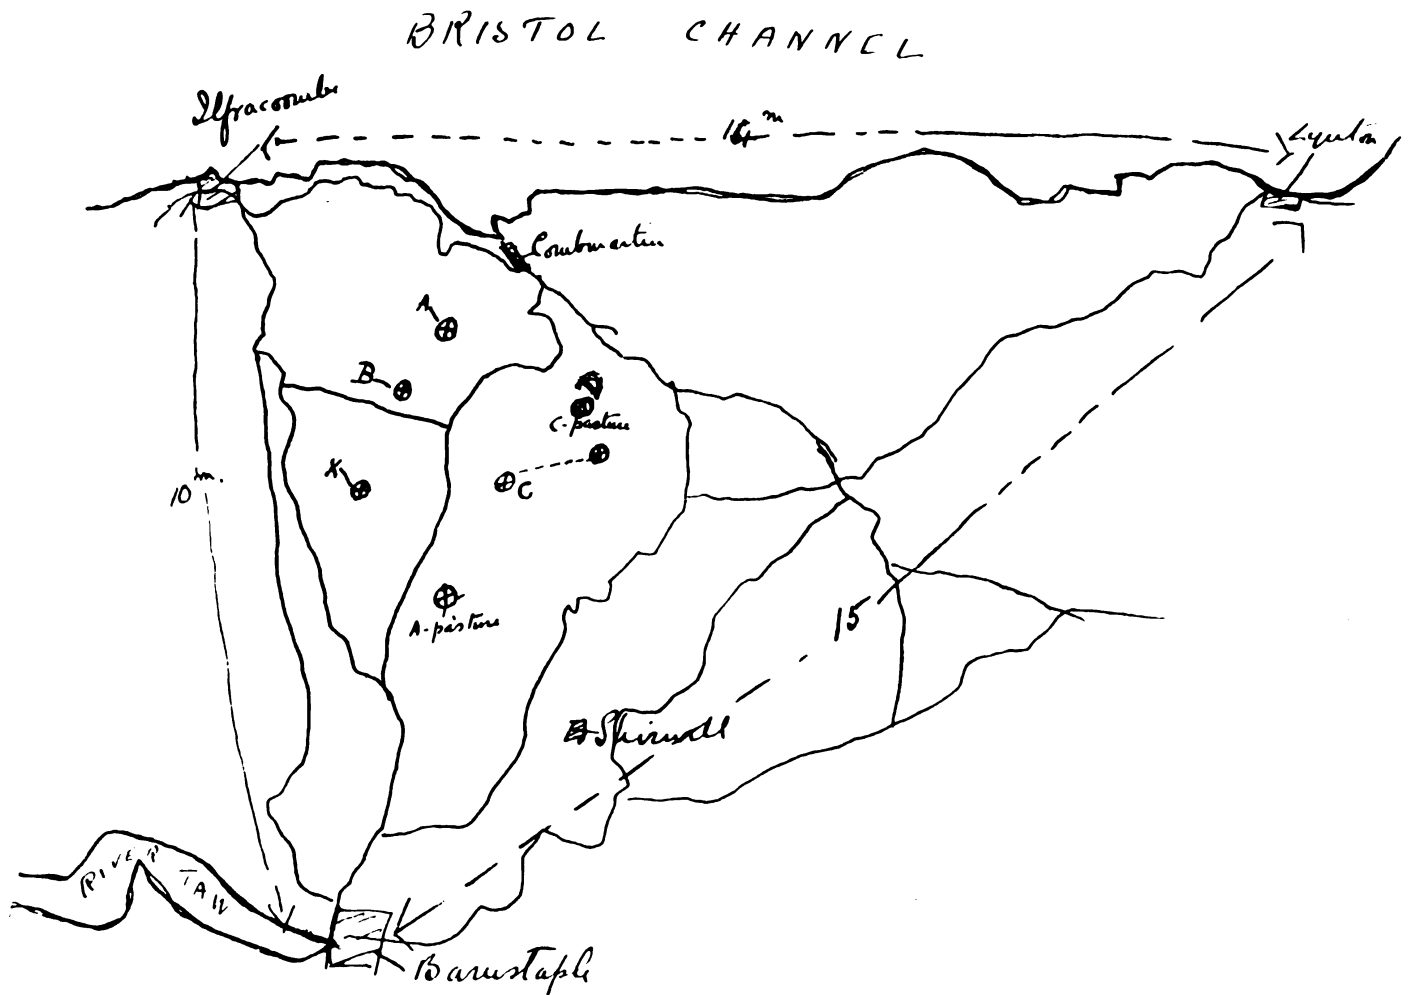

In this outbreak several animals were attacked, and of these some showed peculiar features. There was a suppurating of the udder, and a swelling of the fore and hind limbs terminated above, quite sharply, by the knee and hock. Specimens of one case were forwarded to M'Fadyean, who states in a footnote to Gair's article that he found numerous coccidia in scrapings from the mucous membrane of the portion of the large intestine sent him. As to the species of coccidium he makes no mention, though Gair speaks of them as *C. oviforme*. The cases occurred in Polled-Angus cattle, but coccidia only appear to have been definitely found in one case.

All the cases which have come under my own observation have occurred in Devons, and the affected area lies roughly inside a triangle, of which the angles lie at Lynton, Barnstaple and Ilfracombe,

and the history of the outbreaks can best be followed by reference to the accompanying map.

The disease, or rather the appearance of cases of dysentery in cattle and young stock each summer, seems to have been familiar to some farmers in this district for many years. My attention was first called to it in July, 1911. At this time I was consulted about an animal on farm X, showing the following symptoms: arched back, straining, profuse diarrhoea, faeces freely mixed with blood, and temperature slightly raised. The case was treated as one of acute digestive disturbance. The animal died a few days later, and I was unable to make a post mortem examination.

In 1912 an outbreak occurred on Farm A. The owners had been in possession here for about 14 years, and had not encountered any similar trouble with their cattle. The affected animals were pastured on high dry land marked on map A. (pasture). They were found ill and brought back to the farm, where out of eight affected three died. The symptoms shown were the same as in the case above, while in addition tympany was present in two or three of the affected beasts, and the temperature rose to 105° F. No post-mortem examination was made.

Early in the present year I mentioned these cases to my friend, Mr. G. L. Ingram, when consulting him about the occurrence of Johne's disease in the neighbourhood, and at his suggestion I was led to examine the faeces of the cattle for coccidia at the first outbreak this summer.

The first case this year was seen on farm B. (separated from farm A. by one field) in a heifer 18 months old, and later another case occurred in a young steer 14 months old. The owners have been on this farm for 30 years and have never seen any animals with a similar illness. There are about 15 adult animals, and the same number of young stock on the farm.

Rabbits are plentiful on both farms, and there is a large number of pheasants in the neighbourhood, but no history of disease in either. Sheep, pigs, and poultry on these farms are also healthy.

The heifer was bought as a calf from a farmer in the same village. When first seen by me on July 3rd she showed symptoms of cerebral trouble. She was restless, bored with her head against a wall, had incomplete control of her limbs, and profuse bloody diarrhoea. Her temperature was 102.5 F., and her heartbeats weak and irregular.

On making a microscopic examination of the faeces, innumerable oocysts could be seen in every field, no stain being necessary. This animal died on the morning of July 6th, and a post-mortem examination was made the next day, portions of the various organs being preserved.

A second case occurred on this farm a few days later in a yearling, the only symptoms being dysentery and a slight grinding of the teeth. The temperature was 102.5 F. This animal has gradually recovered.

The next cases occurred at Farm C., the animals being pastured at C. pasture. Two yearlings were first attacked. Again the temperatures were normal, and no other symptoms were apparent except the diarrhoea and passage of blood with arching of the back and some straining at each motion of the bowels. Out of six yearlings on the pasture four were taken ill, brought home to the farm, and isolated. They are now convalescent. In all cases coccidia have been present in the faeces in great numbers. The owner has frequently had the disease on his farm, and has lost a lot of young animals owing to it.

I shot a few rabbits on the farm and found the livers of three half-grown ones to be extensively infected with oval coccidia.

More recently I have been called to farm D. This adjoins C. pasture, and the owner has no recollection of any such affection during the last 24 years. He has 17 young beasts, and of these at the time of writing three are affected, coccidia being easily demonstrable in all. One animal, which had been ill for a week before I was consulted, showed cerebral symptoms, exactly as in the first case on farm B. All now show signs of recovery.

Some authorities suggest that the cerebral symptoms and high temperature are due to the parasites denuding the bowel of its epithelial lining and so allowing secondary infection and toxin absorption.

Referring again to Gair's cases, it is of some

interest to note that I have at present a three-year-old in-calf cow showing painful swelling of the limbs, marked mammitis, a temperature of 105° F. and some difficulty in rising, but up to now no signs of diarrhoea. This case is some ten miles from the affected area.

From a meat inspection standpoint, Ostertag (Handbook of Meat Inspection) mentions that the meat of animals subjected to emergency slaughter on account of "red dysentery" as it is called in Germany and Switzerland, is always admitted to the markets and eaten without any bad results. This is an argument against the parasite resembling *C. oviforme*, which has been found in cases of coccidiosis in man, being identical with the coccidium in these cases or with that of the rabbit.

I have to thank Dr. C. C. Twort (Beit Memorial Fellow) of the Brown Institution, for kindly confirming the presence of coccidia in faeces and in sections of affected intestine, and I hope later to be able to supplement the above brief notes.

ABSTRACT FROM FOREIGN JOURNALS.

THE RELATION OF ANIMAL FAT TO TUBERCLE BACILLUS FAT. — W. C. WHITE and A. M. GAMMON (*Jour. Med. Research*, 26 (1912), No. 2, pp. 257-266).

In this paper the results are reported of a preliminary study of the behaviour of various animal and vegetable fats—stearic acid, palmitic acid, linolic and linoleic acid, and butter and human fat—with tubercle bacilli growing on glycerine agar. Olive oil was used as a source for the oleic acid, palm oil for the palmitic acid, linseed oil for the linolic and linoleic acids, and beef suet for the stearic acid.

On the basis of the results obtained, the authors suggest an explanation for the caudal lobe lesions in cattle, and the apical lesions in tuberculosis of man, as follows:—The pulmonary artery, before dividing into the right and left pulmonary branches, forms a great bay of blood bounded by a very elastic wall. The blood in this portion of the pulmonary artery must move with comparative slowness, because of the short circuit which it makes in comparison with the long circuit made by the general aortic quota of blood. In this great bay the blood is loaded with fatty derivatives of low specific gravity compared with the whole blood. Owing to the slowness of the current, these compounds have a chance to rise to the surface of the stream, so that the upper layer of blood in the pulmonary artery should have a much larger content of fatty compounds than the lower one. At the highest point of this main blood stream in man the vessel arises that supplies the apex of the upper lobe on either side, so that if the theory advanced be correct, this vessel should be the vessel most laden with the fatty compounds of low specific gravity which are being poured into the pulmonary stream of the liver mechanism. "This view, coupled with the results of our experimental work

so far completed, which shows that the tubercle bacillus makes use of these compounds for its more abundant growth, seems a most reasonable explanation of its more prevalent development in the apex of the upper lobe."

TOXIN FORMATION BY THE ANTHRAX BACILLUS.—

A. MARXER (*Ztschr. Immunitätsf. u. Expt. Ther.* 1, *Orig.*, 13 (1912), No. 4, pp. 309-328).

Asporogenic anthrax bacilli produce a heat-stable endotoxin in large amounts. Spore-forming varieties yield the toxin only in small amounts. By injecting this toxin into animals, symptoms are produced which simulate those produced by Friedberger's anaphylatoxin, or from an extract of the typhoid bacillus (Aronson's extract). The urine from the animals treated with the endotoxin and presenting the symptoms of shock, when injected into other subjects produces typical anaphylaxis. As with the endotoxins of some other bacteria, the treatment of animals with the endotoxin produces no antitoxin in the blood.

DIAGNOSIS OF ANTHRAX WITH AID OF THE BONE MARROW.—F. WULFF (*Berliner Tier. Woch.*) 28 (1912), No. 24, pp. 421-423.

The bone marrow taken from either the diaphysis or epiphysis can be used for detecting the presence of the anthrax bacillus for the purpose of diagnosing the disease. The method proposed gave positive results in instances where the blood or spleen was negative.

AUTO-SEROTHERAPY IN EQUINE PLEURISY.

Haan has published (*Revue Gén. de Méd. Vét.*) an article upon this subject. Auto-serotherapy in sero-fibrinous pleurisy of the horse is not a new therapeutic method, but it seems to be little applied by practitioners.

Haan has obtained such good results with it that he advises all to have recourse to it. Without claiming infallibility for it, he says that it has enabled him to obtain miraculous recoveries in cases that seemed hopeless.

Haan briefly reviews the clinical evolution of pleurisy—complete anorexia, violent fever, and injected mucous membranes. It is only about the fourth or fifth day of the malady that it is possible to discover an effusion and to attempt its puncture. Often the pleurisy only appears later, being a sequence of pneumonia.

The author lays stress upon one sign, which he regards as being of capital importance in diagnosis. This is the behaviour of the temperature, which remains stationary and invariable at 39° C. (= 102.2° F.) without any fluctuation during the formation of the exudate. The two signs of the temperature and the contracted fascial expression of the animal suffice to establish the diagnosis. The eyes appear to project from the orbits; and the wings of the nostrils show a characteristic saw-saw movement, in which the action of the great super-maxillo-nasalis muscle may be distinguished

with extreme clearness. This dilatation of the nostrils is totally different from that which is observed in pneumonia. After the appearance of these symptoms, the clinical examination of the chest rarely fails to corroborate the diagnosis of thoracic effusion.

In addition to the classic methods of treatment (caffeine, digitalis, diuretics, vesicatories, etc.) Haan has always practised thoracentesis followed by auto-serotherapy. He withdraws by puncture as much as possible of the thoracic liquid, and then injects at least 40 c.c. of it into the subcutaneous connective tissue. From the day after this measure there is a sudden amelioration, shown by a return of the appetite and a very distinct fall of the temperature. If necessary, the operation is repeated at the reappearance of the effusion.

By this method, applied early before the liquid is transformed into pus and before the formation of coagula and of adhesions, it is possible to save nearly two-thirds of the patients. In favourable cases, the resorption of the effusion is complete in from six to ten days.—(*Annales de Méd. Vét.*)

W. R. C.

THE CENTRAL VETERINARY SOCIETY.

The ordinary monthly meeting was held at 10 Red Lion Square, London, W.C., on Thursday, 3rd July, Mr. J. W. McIntosh, president, occupying the Chair.

The following Fellows signed the attendance book:—Messrs. R. J. Foreman, G. Gordon, Vet.-Capt. G. Rees-Mogg, H. J. Parkin, R. Eaglesham, J. B. Buxton, R. Bryden, J. Willett, W. Perryman, P. W. Dayer-Smith, W. S. King, A. E. Willett, H. D. Jones, C. H. Sheather, B. Gorton, A. L. Wilson, F. W. Willett, Prof. J. Macqueen, S. H. Sloccock, Prof. E. B. Reynolds, W. R. Clarke, N. Almond, T. C. Garry, H. K. Roberts, Prof. F. Hobday, F. J. Taylor, L. Auchterloine, Col. L. J. Blenkinsop, R. A. Philp, P. S. Howard, C. E. Wells, Guy Sutton, W. R. Davis, A. E. Gostling, and Hugh A. MacCormack, hon. sec.

Visitors: Messrs. E. L. Siddall, E. L. Dixon, W. B. Nelder, R. B. Nelder, A. R. Routledge, W. Robinson, H. Sumner, G. H. Banham, J. Dunstan, R. D. Williams, T. C. Toope, J. McKinna, Capt. H. S. Mosley, G. P. Male, and T. M. Parker.

On the motion of Mr. Almond, seconded by Mr. Willett, the minutes of the last meeting were taken as read and confirmed.

CORRESPONDENCE.

Letters regretting inability to attend were received from Messrs. T. S. Price, G. H. Livesey, C. Roberts, and A. E. Payne.

A pamphlet had been received from Mr. A. S. Leese, M.R.C.V.S., camel specialist, Civil Veterinary Department, Sohawa, India: "Some more successful experiments on the treatment of surra in the camel, with recommendations for systematic treatment."

The SECRETARY, on the motion of the President, was instructed to acknowledge the receipt of the pamphlet and thank Mr. Leese.

MORBID SPECIMENS.

Mr. SLOCOCK exhibited a testicle (sent to him by his son) weighing 7½ lbs. removed after death from a three-year old colt which had been relieved of the other testicle when he was a yearling. His son, while acting as *locum*, was requested to castrate the colt in the way

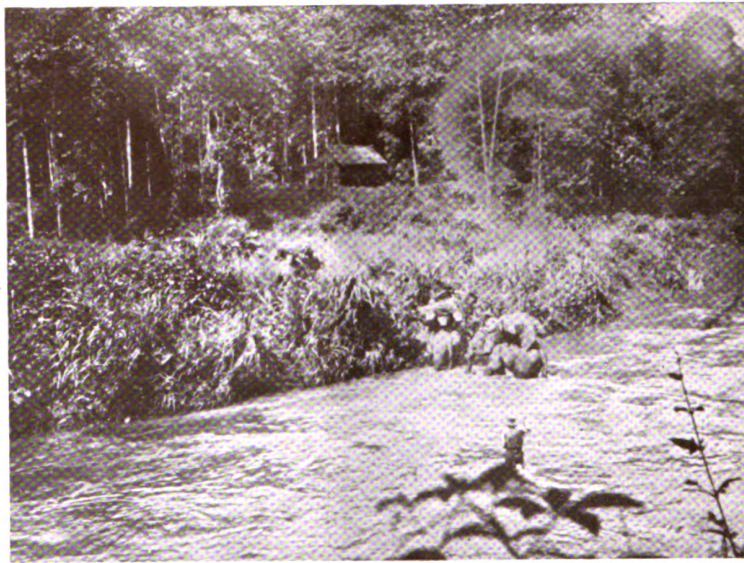

UNIV. OF

MARE MULE WITH FOAL.

Illustrating note by G. J. Harvey, Govt. V.S., Nicosia, Cyprus.

TO THE
ASSOCIATION

CROSSING A RIVER ON ELEPHANTS IN INDIA.

From photos by Mr. F. Ware, I.C.V.D. (p. 70.)

he thought fit, as the colt was useless in his present condition. He was told the testicle had been in the scrotum, and that it had been visible. He was doing the operation standing, and on manipulation he felt a body which did not seem to him quite of the nature of a testicle. He cut into it, and a little fluid spurted out. He explored the inguinal canal with the hand as far as he dared, and, feeling nothing, he decided to cast the colt. Previous enquiries as to whether there had been any sign of rupture elicited a negative reply. During casting, several feet of intestines presented themselves. He then explored *per rectum*, but he could find no sign of an abdominal testicle. The intestines had got into a dirty condition. He advised the owner that the only thing to do was to kill the colt, and on that being done and a post-mortem examination being made the testicle exhibited presented itself just above the colon. His son desired Prof. Macqueen to accept the testicle at the conclusion of the meeting. He hoped some of the members would be enabled to throw some light on the question of what the nature of the disease was.

Mr. H. A. MACCORMACK exhibited a specimen of the trachea of a turkey about eight weeks old, from which it would be seen that the tube was simply crammed full of gape worms. Gape worms were found in all domesticated birds; he had also found them in the starling, and about two months ago he found them in a thrush, the interesting point in connection with the latter being that it was a hand-reared bird, about ten weeks old. How the worms got in he could not form an opinion.

Prof. F. HOBDAY said that by a curious coincidence he happened to have had four cases of very large cryptorchid testicles during the last four months. Two of them were nearly as big as the specimen shown, and one was quite as big. They were all in the abdomen. The one which was just about the same size as that shown was of especial interest because he could not get it away except by breaking it up into pieces. When he got his hand inside, he could feel a huge thing which he could not lift up with one hand. He scratched at it for some time with his nail, and managed to rupture one of the cysts, but eventually he took a small Symes' knife, carefully introduced it in his hand into the abdomen with a portion of the blade wrapped with wadding, and after using it pulled the testicle out in three pieces. That testicle had inside it pretty nearly every abnormality met with in "rig" castration. It was enlarged by tumour tissue; it was cystic; it had some teeth; it had some pieces of bone; a perfect specimen of the *strongylus armatus* worm; the only thing that was missing, which was sometimes found in these specimens, being hair. Each case had done well. In all such cases for the last three years he had never even washed the skin; they had each been painted with iodine, which had been allowed to dry on, and that was all the preliminary treatment they had.

ELECTION TO COUNCIL OF NATIONAL ASSOCIATION.

The PRESIDENT reminded the Fellows that the subject of the election to the Council of the National Association was brought before the last meeting, and deferred in order that the matter might be inquired into, owing to an objection raised by one of the Fellows. The Secretary communicated with Prof. Gofton of Edinburgh on the subject, who had sent the following reply:—

"Yours was duly received, your representatives to the Council N.V.A. should have been elected, and their election intimated to the General Secretary 'not later than April 30th of the current year.' This addition to the rule with respect to date was made in proper form at last annual meeting. The newly-elected representatives take office at the termination of the annual general meeting."

The Society was therefore quite in order at the last

meeting in proposing to elect members to the Council and he would now be glad to receive nominations.

The following gentlemen were nominated and duly elected as representatives of the Society to the Council of the National Association:—Messrs. J. W. McIntosh, R. J. Foreman, S. H. Slocock, Prof. J. Macqueen, W. R. Davis, and J. Willett.

DEMONSTRATION OF A NEW ELECTRICAL APPARATUS FOR THE ADMINISTRATION OF CHLOROFORM VAPOUR, AND DESCRIPTION OF A CHLOROFORM MASK, SUITABLE FOR THE HORSE EITHER WHEN STANDING OR CAST.—By Prof. F. HOBDAY.

Prof. F. HOBDAY, in giving the demonstration, said that some fourteen years ago he introduced to the Society of Anaesthetists a little apparatus which was originally intended for the administration of chloroform to small animals, and he claimed for it at the time that any man with an average amount of knowledge could safely anaesthetise the dog without running any very grave risk. As a student he was always taught that the dog was an animal which could not be chloroformed with safety. On getting his Professorship at the College, for two years he worked with the object of proving that the dog could be chloroformed with safety, and it was everywhere acknowledged at the present day that the dog was one of the best subjects for chloroform anaesthesia if only the chloroform was given in the proper manner. In his early days he was taught to give the chloroform either with a drop bottle, or more commonly by putting some on wadding which was held to the dog's nose, the dog being held by one or two men instead of being in a proper position for the lungs to have free expansion, and over and over again death was the usual result. When his little apparatus was shown to the Society of Anaesthetists, it was very favourably received by several of the best human medical anaesthetists as of value for women and children. It gave, according to calculations made by Dr. Symes, from 1.9 to 2 per cent. of chloroform vapour, thoroughly mixed with air, in such a way that the vapour was practically regular throughout the whole of the chloroformisation. Another advantage was that instead of having chloroform dropped on to lint, and being apt to cause blistering on the part which it touched, it was impossible to have any effect of that kind, because only the vapour was administered. The chief disadvantage was that the manipulation of the rubber ball made one's wrist ache. At that time he had a battery which worked a pump, by means of which he administered chloroform in a similar manner to the new electrical apparatus he was about to describe, but it was continually getting out of order, and he had not time to then complete the idea. A short time ago he again took the matter up, and with the help of certain ideas from an electrician, a small portable apparatus had been evolved, which could be used in country places by medical men or veterinarians for anaesthetising a patient in a house where electrical energy was not available, merely by going to the trouble of carrying the weight of the accumulator. Except for the accumulator and a small motor, there was practically nothing else for the doctor to carry, and if he was going to a house where electric light was installed, provided the voltage was right, the accumulator was not necessary, as there was no difficulty in fixing a connection into one of the lamp sockets. Some little discussion arose in regard to the bottle, as to whether the amount of vapour which came over was constant. In order to get over that difficulty, a little bottle had been made on the same principle as the ordinary siphon chicken feeder, by means of which the chloroform was kept at a constant level. It was fitted on to the side of the little motor, and when the current was put on, a constant stream of vapour was obtained without any

labour; while by means of the regulator, from 1·5 up to 5 per cent. could be obtained with exactitude.

The horse chloroform mask he exhibited was one he happened to see a short time ago when operating at Exeter in consultation with Mr. Nelder. He was particularly struck with the fact of how very quietly the animal took the chloroform from Mr. Nelder's mask, and how very quietly he went down. In this particular case the mask was put on a hunter about 17·1 hands high, in his box, not outside; it was allowed to remain on for about ten minutes, ten minutes being the average time; the animal was then taken out into a small yard and did not give the slightest trouble. It would be seen that the mask consisted simply of a canvas nose-bag, with holes at the bottom, and a piece of felt, which was eventually curved with a removable leather bottom.

He also exhibited a mask which Mr. F. J. Taylor had used a great deal, which varied in pattern from Mr. Nelder's, and as Mr. Taylor was present that evening he would explain its principle.

Mr. W. B. NELDER stated that he had the muzzle made for chloroforming colts in the standing position. The canvas bag with the holes in the bottom is put on first, a restive colt does not object to it as he can breathe quite easily through it, so does not frighten him. The animal is then led out into the operating yard. The leather tray with a thick piece of felt, to the latter two or three ounces of chloroform having been added, is quickly attached by the two buckles to the bottom of the muzzle. In some cases the complete muzzle, with chloroform, can be fixed on in the stable, and the animal then led out. You will find your patient will not fight in the least if he is allowed to have his head. Do not pull him about, he will go round in a ring and then go down quietly. That is the secret, if any. By the time the operator has his instruments ready the colt will be ready to go down. Of course, some animals take more chloroform than others; when this is the case, add a little more chloroform to the felt; some animals, too, take longer to go under.

If you wish to exclude the air completely, just wrap a towel round the muzzle. This apparatus is not elaborate in any way, it is quite a simple little affair, but is a very useful thing for a veterinary surgeon to have, especially in a practice where help is scarce, and he has to tie the colts himself.

Mr. F. J. TAYLOR, London, in describing his muzzle, said it was a very cheap one, as it cost only about 7s. 6d. or 10s. It was, he thought, a slight improvement on the old Cox muzzle, inasmuch as it had a septum of galvanised perforated metal in the centre, which prevented the chloroform from coming directly into contact with the end of the horse's nose, and also prevented the mucous discharges from the horse's mouth and nose saturating the wool, and so hindering proper evaporation of the spirit. It possessed other advantages over some other patterns, inasmuch as the horse's tongue could be got at if necessary, and the metal disc when in use blocked the leather cylinder away from the nostrils, and allowed of free inhalation, and when not in use the fact of its being on hinges allowed the muzzle to be packed quite flat for carrying.

Mr. SHEATHER remarked that in about 1879 his father invented an apparatus on similar lines to that shown by Prof. Hobday, only it was worked by foot bellows. He had to give it up because the labour of pumping with the feet was just as great as pumping it with the hands, but the apparatus was very similar in construction to Prof. Hobday's.

Colonel BLENKINSOP said that some twenty-three years ago, with the late Colonel Nunn, he used at the Lahore Veterinary College an apparatus for chloroforming horses very similar to that shown by Prof. Hobday, except that in their case the air was driven through the chloroform instead of over it. They brought the

apparatus home and found that a few weeks before their arrival a similar apparatus had been made in England. Twenty-five or thirty years ago he was probably using chloroform more frequently than anybody else in the profession. At that time he operated upon hundreds of castration cases, and he never saw an accident to a horse under chloroform with any sort of apparatus. It is different, however, with dogs. He congratulated Mr. Nelder on producing such an excellent muzzle. He confessed he had had very little success personally when chloroforming horses standing, and up to now he would prefer to throw a horse before administering an anaesthetic, but with Mr. Nelder's muzzle he hoped to be able to administer chloroform without casting patients. He congratulated Prof. Hobday on his apparatus. It must be borne in mind in giving chloroform to a horse that as a rule the sooner the patient was got under the anaesthetic, the sooner he came to. If a long time was taken in giving the chloroform, the horse was a long time recovering.

In reply to questions by Mr. Willett, Prof. Hobday stated that the price of a single apparatus would be, as far as could be at present estimated, £2 or £2 10s., with £3 3s. as the very utmost. The battery lasted for twelve hours, but it would not be necessary to use a battery where electrical energy of the proper voltage was available, and by having a little addition to the apparatus it was possible to adopt it to any of the different voltages which existed.

Mr. ALMOND said he remembered when he was a student seeing horses chloroformed standing, sometimes with disastrous results, not only to the horses but to the men in charge of them. It is important that the Fellows should understand how it was that in the hands of some practitioners the very greatest trouble was met with under those circumstances, while in the hands of others the procedure was perfectly satisfactory. Mr. Nelder's view that that the trouble arose from the restraint put upon the horse, whereas if the horse was chloroformed and allowed its freedom, except for being on a loose halter, it quietly laid down and gave no trouble.

Prof. MACQUEEN raised the point as to whether the present discussion was in order, seeing that the agenda stated that a paper was to be read upon "The Veterinary Profession and the Animals Anaesthetics Bill." He suggested the paper should be read first, and in the following discussion incidental remarks regarding chloroform muzzles could be included.

The PRESIDENT thought it would expedite matters if the paper was read, although he was of the opinion that the discussion up to the present had been quite in order.

"THE VETERINARY PROFESSION AND THE ANIMALS ANAESTHETICS BILL"—By Prof. F. HOBDAY. [This appeared at p. 56.]

DISCUSSION.

Mr. J. DUNSTAN, in opening the discussion, thought the paper was of interest to country as well as to town practitioners. Country practitioners were faced with a good deal of practice by unqualified practitioners, which was increasing rather than diminishing. By means of Prof. Hobday's apparatus greater facilities would be obtained for producing anaesthesia. Some of the elaborate appliances shown were quite unnecessary to owners of motor cars, because by means of a little switch to the motor car they could easily generate the power. The apparatus was a great improvement on the old hand-bottle method, especially the being able to increase the proportion of chloroform up to 5 per cent. The small percentage of chloroform obtainable from the old bottle necessitated a great amount of time being spent in anaesthetising a large animal, and matters were sometimes hurried by means of a saturated plug. He

had an exceedingly useful chloroform muzzle which was given him by a New Zealand practitioner, which he hoped he might be allowed to exhibit on a future occasion. He was very glad to find that someone was taking an interest in the Anaesthetics Bill with the object of getting the promoters to look at the matter from the veterinary side, because some of the suggestions made in the original draft were utterly ridiculous, and it was easy to understand the feeling which promoted agriculturists and farmers generally to protest against its provisions. The administration of chloroform to a fairly old bull was unnecessary. He was recently asked by a farmer to watch him operate upon a dozen bulls about a year old. The bulls were tied up side by side in an ordinary byre, with a man holding them by the nose and horns. The man walked behind them with an ordinary scalpel, made a slit into the scrotum on one side, letting out the testicle, and then on the other, letting out the other testicle; he tied a wet piece of ordinary worsted round, and just cut them off with his knife. In only one case did the animal move, in fact the animals did not seem to resent it at all. He was very much struck with the standing operation on the bull; it was the first time he had seen it performed.

Capt. REES-MOGG asked if the Members of Parliament who drafted the Bill did it with the assistance of any members of the veterinary profession. If not, to ask the veterinary profession after the Bill had been drafted to consider the matter, was a little late in the day. The veterinary profession should have been consulted before the Bill was drafted.

Col. BLENKINSOP said that he had been in the fortunate position of being able to use chloroform or any other anaesthetic in operations on animals whenever he considered it necessary to do so, and had not had to consult clients. He thought the veterinary profession should go very warily in opposing or adversely criticising this Bill. Public opinion was daily growing stronger against the infliction of unnecessary pain on animals. Veterinary surgeons should be encouraged by this, as the primary object of their profession was to succour animals. They should be the first to advocate the more general use of anaesthetics. He could not understand how any person could logically say that the necessity of administering anaesthetics to horses could be limited to those of two years and over. Colts under that age were capable of suffering acute pain. The fact that a horse would eat immediately after an operation was no evidence that it was not suffering pain. A horse in pain would often eat in order to endeavour to relieve its suffering, in exactly the same way as a wounded man would smoke.

He had castrated horses of all ages, and he objected to castrate any horse without administering a general anaesthetic. He considered the standing operation—the gymnastic operation—was not surgery. A great deal too much was made of the danger of throwing horses and administering chloroform. If statistics were studied it would be found that accidents only occurred in a number reaching a decimal point per thousand of horses cast and placed under chloroform, if this operation was carried out with proper care and with trained assistants.

He thought the profession should have been consulted when the Bill was being drafted, and that it should now uphold its dignity as a profession by insisting on being consulted. The profession suffered greatly from having none of its members in the House of Commons, an old grievance which constantly cropped up when questions affecting animals were the subject of legislation.

Mr. W. R. DAVIS did not believe it was the intention of the profession to offer any great opposition to the measure. At same they must be allowed a great deal

of discretion as to what anaesthetic should be used and what operations it should be used in. For instance, nothing was said about the administration of chloroform in cases of parturition, or inversion of the uterus in mares or cows, or cases of colic, where there was ten times more suffering than in castration. The Bill would give a handle with which to control the quacks, who did far more to cause suffering amongst animals than would be brought about by giving veterinary surgeons discretion to use chloroform or not as they thought proper. He did not agree with Professor Hobday that when a horse was castrated standing, it was all over. If caustic clamps were put on, it was not over by any means, so far as pain to the animal was concerned. With regard to animals apart from horses and cows, veterinary surgeons should be allowed to say whether they would give chloroform or not in those cases. The degree of narcotism produced was another point that had to be considered. Chloroform could be given to a horse, and as much trouble and pain be obtained as if he had been given none at all. If quacks especially were to be allowed to give it, what was to prevent them buying a chloroform muzzle, putting on half a gramme or one gramme of chloroform and letting the horse have a sniff at it and say chloroform had been given?

On the motion of Mr. Almond, seconded by Mr. Jones, it was resolved that the meeting should be prolonged in order that the discussion on the paper might be concluded.

Prof. REYNOLDS thought it would not be advisable for the veterinary profession to make a lot of objections to the Bill, because the public would think they were against the use of anaesthetics. Mr. Davis had suggested that the Bill should be allowed to pass because it would give a leverage against the quacks. To accomplish that purpose it would be better to pass a Bill to prevent unqualified men doing any operation at all on animals, but to tie veterinary surgeons down to what operations they should perform under an anaesthetic and to what anaesthetics they should use was more or less absurd. The Bill, it had been said, had been promoted without prejudice against qualified veterinary surgeons, but the preamble stated that it was a Bill to make further provision for the protection of animals from cruelty, which was a direct accusation against veterinary surgeons of causing cruelty to animals. If the promoters had consulted veterinary surgeons before drafting the Bill they would not have made a number of the mistakes that have occurred. He believed the original Bill was conceived in the Officers' mess of a Territorial Yeomanry regiment, where the officers discussed with the veterinary officer various operations that are performed and the anaesthetics that are used. The first Bill was so unworkable that it was certain not to go through Parliament. After some veterinary surgeons had been consulted, a great improvement was made in it. He agreed that veterinary surgeons should not object to the Bill on the ground that they objected to using anaesthetics, but should object to it on the ground that they should be compelled to use them and told the operations for which they were to be used, so allowing them no discretion. A point in connection with the Bill was that animals were looked upon from the commercial side; the value of an animal entered into the consideration of the owner, and if there was going to be any increased risk of accidents it made a tremendous difference. Col. Blenkinsop had referred to the standing operation, which he had called gymnastic, and which he had described as being non surgical. Mr. Davis had referred to it as acrobatic. Personally, he happened to be an advocate of the standing operation, and he was quite certain that it was not acrobatic nor gymnastic, and that it was just as surgical as the ordinary operation done on the ground.

Mr. DAVIS, interposing, said that his objection to it was that the pain was not over when the clams were put on.

Prof. REYNOLDS, continuing, said that while that statement was more or less correct, the operation was not always done with clams. He did not say the horse suffered less pain during the actual operation when castrated standing than when castrated on the ground, but if the sum total of pain that he suffered was taken into account, it was less when the operation was done standing than when the animal was cast. He desired to know who was going to see that the Bill was carried out if it became law. Who was going to certify whether the animal was or was not under complete anaesthesia while he was operated on? ("The Police.") He believed that neither policemen nor inspectors of the Society for the Prevention of Cruelty to Animals were allowed to walk on to private property, and he thought something more definite should be stated in regard to the carrying out of the measure.

Mr. TOORE inquired whether any law existed relating to what operations should be or should not be performed by medical man, under chloroform; and if there was none, why there was none?

The PRESIDENT desired in the name of the Society to thank Prof. Hobday for introducing the subject, and thus giving an opportunity of discussing the Animals Anaesthetics Bill. It was extremely unfortunate that the profession had not been taken into account when the Bill was framed. The matter was kept in the dark for a very considerable time. He was quite sure no veterinary surgeons had any desire to block the path of human progress, but surely for a body of laymen to introduce a Bill of this kind and ignore the profession in framing it was altogether absurd. The provisions of the existing Bill he thought sufficiently wide and definite to cover the matter. A good deal had been said on the subject of castration. He had done a good many colts in his day, and had always done them standing, being a great believer in the standing operation, because he thought the animal suffered less than when cast and chloroformed. He used the caustic clamp with the greatest success, and whether it be good surgery or not—nothing succeeds like success. After the operation was completed the animal went and took his food as if nothing had happened. In some cases it would be found that after the effects of the anaesthetic had passed off—when anaesthetics were used, there was a considerable amount of pain, so that pain was present in animals that had been operated on under anaesthesia as well as those which were operated on without it. He resented being told when to use an anaesthetic and in what operation. Even if the Bill passed, who was to see its provisions were carried out. No police officer or other officer has power to enter private premises unless they had an order from the magistrate, and then they must have some suspicion that cruelty was being perpetrated. There was no machinery for carrying out the Bill even if it became law, and it would be necessary to trust to the profession even then.

Prof. MACQUEEN strongly agreed with what had fallen from Colonel Blenkinsop. He thought the question was one upon which the veterinary profession should not take sides as against the administration of general anaesthetics. There was no operation that could be performed without anaesthetics that could not be performed under anaesthetics, and although there was a disposition on the part of the promoters of the Bill to exempt very young animals from operations under general anaesthesia, to be logical, both the young and the old should undergo that method of restraint. The President stated that the veterinary profession was founded upon humanitarianism. Upon that foundation a very large edifice of commercialism had been raised, and the difficulty of the profession in approaching the

question was very similar to that which affected some of the Marconi speculators. They were not sure whether by supporting the Bill it would be considered speculation or a professional investment, but he thought the promoters of the Bill ought to be given, he would not say their undivided support, but their moral support in the statement that general anaesthesia was always advisable. That was the attitude the members of the veterinary profession were sure to take before the public, whatever the practice behind the scenes might be. Professor Hobday had referred to some information supplied to him by two lay promoters of the Bill. He agreed with the President that if the promoters desired to produce a Bill which would meet with the general approbation, not only of the veterinary profession but of the cattle-owning public, they ought to have consulted some modern veterinary practitioners.

He understood that one aim of the Bill was to leave the question largely to the Board of Agriculture; the Board of Agriculture were to determine what operations should be performed under a general anaesthetic, and what operations might not be so performed. The regulations would be carried out under the supervision of the police. Notice would have to be given when an operation was to be performed; the policeman would attend just in the same way that he paid a call when swine fever broke out. His advice as an individual member of the profession was that the less that was said about the Anaesthetics Bill in the meantime the better. Let it take its course, and when it becomes law they could treat it accordingly.

The PRESIDENT, interposing, said it would be too late then.

Prof. MACQUEEN said that late or not it would not seriously affect practice. Unless a policeman was appointed, or notification was made compulsory, there was no one to see how far the anaesthesia had been carried. Anaesthesia to one individual in the profession was a very different thing from anaesthesia to another. It seemed to him they were only wasting time trying to modify a Bill which was not likely to see the Statute Book until a new Government was in power.

Prof. HOBDAY, in reply, said that he understood all the speakers were unanimous in favour of a Bill which would increase the use of anaesthetics for operations on animals, or even compulsorily cause the application of anaesthetics to all painful operations. But the thing which had touched everyone to the quick was that they were being told to toe the line in a manner which they could not do, and which they ought not to be told to do by men who did not know as much about the question as veterinary surgeons did. There was not the slightest doubt that if the Bill became law it would be of benefit to them as a profession. It would not only raise their status by compelling owners of animals to come to veterinary surgeons to have their operations performed in a humane manner, as opposed to the way in which they were conducted all over the country at the present time by quack operators, but there was no question that pecuniarily it would be beneficial to them, although, of course, they did not really look at it from that point of view. The point which had been raised by Professor Almond in regard to the simplicity of Mr. Nelder's mask had struck him greatly. It was the absence of the feeling of restraint and suffocation which formed its practical value. With regard to the question as to whether members of the profession were consulted before the Bill was drafted, he only knew what he had read to them that evening from the letter of one of the chief promoters of the Bill. If the original Bill had been passed, the veterinary profession would have been tied hard-and-foot, and there would have been as much stir in their little profession as there was over the whole of England at the present moment in regard to another Bill. Professor Macqueen raised the point of the

exemption of the young animal. He agreed with Prof. Macqueen that the young animal had just as much right to have its pain respected as an old animal. That was another instance why veterinary surgeons should be given discretionary powers, and should not be told that they must use such and such an anæsthetic for any particular operation, because the young animal was more susceptible to the influence of general anæsthetics, and in some instances it was not wise to use chloroform. In his opinion the word "satisfactory" should be substituted for the word "general" anæsthetic in the Bill. That would give the veterinary surgeon power to choose whether he would give a general anæsthetic such as chloroform, or use a local anæsthetic, and so long as pain was really abolished the aim would be fulfilled. He disagreed with Professor Macqueen's remark that time was being wasted in discussing the Bill at the present moment. If it was left until the Bill became law, it would be too late. Too much power was, he thought, given to the Board of Agriculture to say what should or should not be added. He was not aware of any law by which medical men were told they must use certain anæsthetics for certain operations, and medical men would not be dictated to in that way. With regard to the question of the standing operation, it was no doubt a little anomalous to advocate on humanitarian grounds the use of anæsthetics, and yet to leave out the standing operation as being one which a man advised if he had an expert operator in the district. Personally, he never used the clamps; he always used a Blake castrator, and if he had not now got a little out of practice, and grown a little rotundity in front, he would always have preferred, for the sale of the patient, to operate with the horse standing rather than that the animal should be cast. When the operation was done expertly he had seen both the testicles on the ground in 3½ minutes; the animal went straight back to the manger, and the sum total of fright and pain was not nearly so large as that caused by the casting and the administration of chloroform. In many hundreds of instances the beast never turned a hair when the standing operation was performed, whereas when a colt was thrown and chloroformed he was usually very frightened. It must be remembered too that it was results that had to be considered in veterinary practice. Colonel Blenkinsop said he never would operate without an anæsthetic, and did not consider the standing operation a surgical one. Operators select and stick to the method which gives them the safest and best results. The most surgical method of castration was by means of a ligature, but that gave the most fatal results so far as the horse was concerned.

He agreed that the Anæsthetics Bill must be carefully considered before opposition was offered to it. As Mr. Davis had remarked, nothing was said in the Bill about the use of chloroform in parturition, nor in tumours or abdominal operations. It would take up pages if all the operations which had to be done under anæsthetics were inserted in the Bill, and the clauses should be in more general terms in order to include these. It was important that the administration of anæsthetics should be properly taught. A number of operations were done under complete and proper anæsthesia, but he had seen instances where the animals were simply given a smell of the chloroform in order to satisfy the prejudice of onlookers.

With the permission of the meeting, he desired to move:—"That the under-mentioned resolution be sent to each of the Members of Parliament, who are the promoters of this Bill:—

"That this meeting of the Central Veterinary Society emphatically favour the compulsory use of anæsthetics in all painful operations upon animals, wherever such is possible, with reasonable safety to the patient. They consider, however, that discretionary power should

always be given to properly qualified veterinary surgeons in the use of anæsthetics. They also think that a number of practising veterinary surgeons should be consulted before the Bill goes into Committee, with a view to making the clauses of such value that they can be adopted practically."

Col. BLENKINSOP seconded the motion.

After a discussion upon this, it was decided that instead of sending the resolution to the promoters of the Bill it should be sent to the Council of the Royal College of Veterinary Surgeons.

Mr. SLOCOCK thought it was a question whether the Central, which was one of the biggest Societies in the profession, should directly support a Bill of that nature. All the members were in favour of anæsthetics being largely used in veterinary practice, certainly in most of the major operations, but in view of the fact that the profession was credited with fathering the first Bill to the detriment of the quacks, and in that way met with opposition from many of the agricultural bodies of the country, he thought it was not desirable that they should take up an attitude of such strong support. He thought they would do better if they simply sat quiet.

Prof. MACQUEEN moved as an amendment:—"That no action be taken in the meantime regarding the promotion of this Bill." In the present stage of their knowledge regarding the various clauses of the Bill he thought it would be unwise to take action. The Society ought to be acquainted with the names of the promoters, the names of the veterinary surgeons who had supplied such very scant information to the promoters, whether the Board of Agriculture had been consulted, and what their views were on the subject. He considered the suggested action was premature.

Mr. MCKINNA suggested that if any action was taken at all, the resolution should be sent to the Royal College of Veterinary Surgeons, which was carefully watching the Bill in the interests of the profession. It would strengthen the hands of the Council if that were done.

Mr. SLOCOCK seconded Professor Macqueen's amendment.

Professor HOBDAV, with the permission of his seconder, altered the preface of his resolution to read:—"That the undermentioned resolution be sent to the Council of the Royal College of Veterinary Surgeons."

Prof. MACQUEEN's amendment, that no action be taken, was then put and lost, 12 voting for; and Mr. Hobday's amended resolution was put and carried, 16 voting for.

On the motion of Mr. Willett, seconded by Mr. Reynolds, a hearty vote of thanks was accorded to Prof. Hobday for his paper, and to the gentlemen who had shown "morbid specimens," and the meeting concluded with a vote of thanks to the President, moved by Mr. Willett, for the excellent manner in which he had conducted the business of the Society during his term of office.

The PRESIDENT, in acknowledging the compliment, thanked the members for the support they had given him during the year, and particularly very sincerely thanked their energetic Secretary, Mr. MacCormack, without whom his work would have been much more difficult. Mr. MacCormack was really the man who conducted the affairs of the Society.

HUGH A. MACCORMACK, Hon. Sec.

Royal (Dick) Veterinary College.

At a meeting of the Board of Management of the Royal (Dick) Veterinary College, Edinburgh, held on Wednesday of last week, Mr. F. P. Milligan, W.S., of the firm of Messrs. Martin, Milligan, and Macdonald, W.S., Edinburgh, was appointed to the vacant post of secretary and treasurer of the College.—*N.B.A.*

ROYAL SANITARY INSTITUTE CONGRESS.

CONFERENCE OF VETERINARY INSPECTORS.

THE MILK AND DAIRIES BILL,*

by WILLIAM ASCOTT, M.R.C.V.S. [ABSTRACT].

This Bill has been so well discussed at the last two sessional meetings it is difficult to say anything fresh; one can only criticise and agree or disagree, as the case may be, with previous speakers.

I may say at once that I am in entire agreement with those who plead for the urgent need of such a Bill, for although I do not believe the case is quite as black as has been painted by some, yet I cannot shut my eyes to the fact that the percentage of cases in which the picture has not been overdrawn is too great to deny the urgent need of more supervision; indeed, my principal complaint is that in at least one important respect, the Bill does not go far enough. Seeing that all urban districts are supplied with milk almost entirely from the rural districts, and also with butter, which, although not included with the definition of milk in clause 26, yet according to clause 12, I take it does come within the meaning of the Act, I am strongly of opinion that the latter—the rural districts—require even more supervision than the former.

The large centres have been much better looked after in the past, and this Act, by reason of its permissive clauses, I am afraid proposes to continue the system. Very few of the smaller urban district councils, and none of the rural, in my part of the world, at any rate, have taken advantage of the powers they already possess, and if the carrying out of the new Act is to be left to them, I am afraid it will be a dead letter so far as most of them are concerned. For this reason I feel very strongly that either the optional clauses should be withdrawn, or the carrying out of the Act be entrusted to those already overworked bodies, the county councils.

I am quite aware there are many difficulties in the way, particularly financial, but that is no reason why our present topsy-turvy system of inspection should be continued. It is surely of equal, if not greater, importance that the source of the supply should be supervised as well as the later process of distribution, and yet the latter is the only part that has hitherto received attention. To tackle the supply at its source is only carrying out the old adage that "Prevention is better than cure."

Taken as a whole the dairies proper, *i.e.*, the places in which the milk is stored, and where unfortunately now, in the majority of cases, the woman's work begins, are pretty well looked after, structural defects are being constantly remedied, and thanks to the excellent work of the dairy schools, there is not much here as a rule to complain of; not but what there are plenty of cases where there is room for improvement, but nothing like to the same extent as before the milk reaches this department.

To begin with the source of the supply, the cow, I am afraid it is only too true that in the majority of cases she is not, especially in the wet and rainy seasons, cleansed as she ought to be prior to milking, and practically the only factor that prevents the use of milk from diseased animals is that it does not pay long to do so in the case of the obviously diseased, and such are soon discarded; but unfortunately there are many others suffering from disease, particularly of the udder, as well as from tuberculosis, which escape detection either wilfully or from want of supervision, and these we hope we should be able to get hold of under this Act, aided as it will be by the Tuberculosis Order of 1913.

* These papers will appear in full in the *Journal of the Sanitary Institute*.

With regard to tuberculosis, those who have not been convinced by the overwhelming evidence adduced by the recent Royal Commission will not be influenced by any words of mine. How can they explain the conclusions arrived at by so many eminent men of the medical profession, particularly as regards the beneficial effect which the reduction of the supply of tuberculous milk has been proved to have on infantile mortality in large centres, such as Manchester? (See an article by Dr. Sheridan Delepine in the *Lancet*, of June, 1912.)

When we come to the cowsheds and shippens I think we are up against the biggest problem, and the most difficult to tackle if the Act is administered too drastically at first, not only on account of the expense but also on account of the inconvenience it would in many cases entail. Unfortunately, it is only too true that there are many cowsheds, especially on the small farms, which are a disgrace to any civilised community; some because they are structurally unfit, and cannot possibly be made fit, seeing that they were constructed for quite different purposes; and many which could be made fit but because, as well as those just alluded to, they are kept in a condition almost too filthy to describe. They are scarcely ever white-washed—some never, and seldom cleaned out properly. In some the dung is piled up in the corners until there is sufficient to make a load; in many it is cast daily out of what should be the window until no more can be thrown out that way; and in the majority of cases, including many that would be quite good otherwise, it is stored in a heap a few feet outside the door for months. In many cases the pigs have one corner of the same shed and the calves another portion, railed off with the beds of each, two or three feet high, composed of the dung which has accumulated for months. Of drainage in these cases there is usually an entire absence, and the stench can be well understood. Now all this should be altered, but it can only be done by means of such an Act as is now proposed. I have again and again, when speaking at agricultural gatherings, urged upon landlords and farmers to do what they could to remedy this state of affairs, but individual effort is of little use. Of course, if the Act is passed, and it is administered properly, there will be plenty of grumbling, but as there is evidently a genuine demand by the public for clean and pure milk, which can only be met by better supervision, the sooner the position is accepted the better for the trader; indeed, the better class trader is only too anxious to do all that he can to help the authorities in every way. I think what I have said about the sheds is a very strong argument in favour of registration, and I agree with those who think it would be best for this to be annual, unless periodic inspection is to be made compulsory.

All that has been said from time to time as to the necessity for cleanliness of the milker is so obvious that I need not dwell on it. It is also equally obvious that supervision is necessary, because, in spite of denials, it is unfortunately still true that the milkers, particularly the men milkers, in many cases neglect the most elementary rules in this respect. One thing has occasionally come under my notice in connection with men milkers, and that is that they are often given this work because they are either too delicate or too ill for rougher work. This, of course, is a part of the medical officer of health's duty, and without entering further into his domain, I think I have said enough to give the discussion a start; but before concluding I should like to say that I agree with those who think the proposed court of appeal may not always be a satisfactory one. A bench composed of landlords and farmers in the rural districts could not be free from bias, although on the whole we must agree that they try to act with the greatest possible fairness.

In conclusion, I wish to emphasise the point I have tried to make, and which I do not think anyone will dispute, and that is that there is plenty of work for the veterinary inspector. Every one must agree that he is the proper person to examine the cows—which at present receive no inspection, and—seeing that he should know more about their requirements than either the medical officer of health or the sanitary inspector, his assistance in inspecting the cowsheds is very desirable, if not essential. For these reasons I think two or three small verbal alterations should be made in clause 2 to make his position quite clear, and I would also lay stress on the necessity of doing away with the permissive character of the Act so far as the rural district councils are concerned, by striking out the whole of line twelve in clause 14 and the first word in the next line.

I would point out that the work would probably be anything but pleasant at first for the veterinary inspector or, indeed, for either of the other inspectors. With regard to his relations with the medical officer of health, I am quite sure he will be found to work in complete harmony with him, and so far from being a hindrance, as has been suggested by one or two, the very nature of his every-day work must make him a most valuable ally.

DISCUSSION.

The PRESIDENT said they need not be deterred from discussing this Bill by the supposition that the measure would appear in the list of the "innocents" that had to die in a very short time. The Milk Bill was before them, and its consideration was no less important now than if there were a chance of the Bill passing; so they might enter on the discussion with as much enthusiasm as though the passing were imminent.

Dr. FREMANTLE, Medical Officer of Health for Hertfordshire, said he only wanted to encourage the gentlemen who knew more about the subject than himself by supporting this Bill. He started by saying how grateful they were to Mr. Ascott for his valuable paper. (Hear, hear). He thanked Mr. Ascott, especially, not only for the conciseness of it but also for the very kind and courteous way in which he had expressed the relationship between the medical and the veterinary profession. (Hear, hear.) He felt that the work of the veterinary inspectors was invaluable to medical officers of health, and he promised Mr. Ascott and those who were veterinary inspectors that they would have no greater friends and better well-wishers and co-operators than the medical officers of health. What they wanted to recognise was that each of them had his own work, that each of them held a kind of watching brief for the community. Medical officers were the first sanitary officers, and from their work had risen a great crowd of officials of one kind and another, but medical officers had only one desire, and that was to put off their work on to other shoulders who were more capable, by virtue of their knowledge and experience, to perform it. That was especially the case with veterinary inspectors. Over and over again they were called upon to give their opinion on matters which related to the work and the special sphere of the veterinary inspectors. They were quite prepared to do it as if they were authoritative, but they much preferred to have the opinion of the veterinary inspector, who was more authoritative still. If medical officers gave their opinion emphatically on little knowledge, the veterinary inspectors would recognise that the medical officers only wished to co-operate with them. (Hear, hear).

As regarded this Bill, they had had it promised them year after year. In August, 1908, in a presidential address which he delivered, he referred to the beneficent measures of the Government who had promised them a Milk Bill. The same thing had occurred every year, and every year the need of it was becoming more im-

portant. (Hear, hear). He could bear out what Mr. Ascott had said as to the condition of the stalls. They expressed their entire recognition of the point of view of the dairy farmer, who said that if Parliament was going to lay a very greatly increased burden of expenditure upon him, although in the long run it might pay when the public recognised the necessity of it, it was a burden he could not bear. Meanwhile, pending this creation of a healthy public opinion, the considerable loss of the dairy farmer might result in some increased expenditure on milk and some deficiency in the supply, if this legislation was carried out in a blindfold way. There was great danger in reducing the amount of milk consumption, or of increasing the expense. (Hear, hear). They must all recognise their sanitary work. It was not simply the few cleanly well-to-do artisans, but those people who seldom consumed pure milk and had the greatest rate of infant mortality and general death rate, who must be safeguarded. Authorities and officials had to deal very tenderly with the question in order to prevent substitutes being offered for milk which were a great deal worse than milk, even if the milk was not exactly clean. He agreed as to the necessity of annual registration for the present. He ventured to call it a license, because license was a better definition in the public mind. They ought to press for the annual licensing of the milk shops and dairies, which would of course make it a matter of routine that they should inspect these dairies every year. (Hear, hear). He thought that that should be impressed upon district councils. Although he stood for County Council Government he did not stand for usurping the work of the district authorities when the district authorities were carrying out their business. (Hear, hear). Taking a military analogy, the brigadier was not going to interfere with the regiment so long as the regiment was well managed. That was the position that the County Council should take up. The County Council should have a watching brief, and power to interfere and responsibility. (Hear, hear). With all this expert service they wanted as broad a basis of work as possible. If a veterinary inspector was appointed by a small district council, managed to a large extent by farmers, it was not giving the inspector sufficient security in his office or a sufficient outlook for his professional service. (Hear, hear). That service should be organised on a large basis. It would be necessary more and more to have a national service, just like a national service for the appointment to various posts to the Army and Navy (Hear, hear.) Inspectors should be appointed on a broad basis of national service, even if they were only part-timers. It must be a national service in which the inspectors should have complete scope and absolute freedom, and if they had, they would be able to attack a vast amount of work. (Applause).

Mr. A. H. ARCHER, Southern Counties V.M.S., said he had perhaps unique opportunities of learning something about this Tuberculosis Order whether it was likely to be carried into effect, and to what extent it would affect owners of stock, as well as the veterinary profession generally.

The PRESIDENT (interposing) said they were discussing the Milk and Dairies Bill, not the Tuberculosis Order; they must keep the two matters distinct.

Mr. ARCHER said the Milk and Dairies Bill would, of course, be at one with the Tuberculosis Order that was now in force. He might say that he had a personal interview with the President of the Local Government Board with regard to it a little over two months since. He knew from the President's personal observations that he was anxious to get any opinions that would assist him in what he (the speaker) might call the inevitable carrying out of the Milk and Dairies Bill when it became an Act of Parliament. No doubt some of the Inspectors who were now carrying out the Tuber-

culosis Order would also be inspectors under the Milk and Dairies Bill. They could run side by side, and he did not see how they were to be kept separate. The effect it was likely to have would be that in many cases the owner would be very much aggrieved, because when the Milk and Dairies Bill came into effect as soon as an animal was notified as suspicious of being subject to tuberculosis, the milk supply must be stopped. That was more serious than the actual loss of the animal. (Hear, hear.)

Under our present system it would take several days to decide whether an animal was tuberculous or not, and that, from the owner's point of view, was a very serious matter, and he thought it was one that should receive consideration, and if anything could be devised to accelerate the decision of the inspectors it should be put before them. (Hear, hear.) He was sure the promoters were willing to welcome any sound practical advice that would advance the popularity and ease the working of the Order and the Bill.

Mr. J. W. McINTOSH, President, Central Veterinary Society, would like to thank Professor Penberthy and Mr. Ascott for the very excellent papers they had submitted. He was an Inspector under the Act, and having been born and bred in agriculture, and an old student, he was much interested in the Bill. He thought they ought to recognise that nothing was more important than that farmers and milk sellers should establish and maintain public confidence in the wholesomeness of what they produced. He was quite sure that all would concede that the legislature was justified in insisting on all reasonable steps to ensure that our milk supply was bought and sold under the best possible conditions. (Hear, hear.) Instead of tardily and reluctantly conforming to any regulations which might from time to time be imposed upon them, they should welcome them. But such regulations should be thoughtfully considered and carefully applied; they must be reasonable, and not calculated to harrass an already over-harrassed industry. (Hear, hear.) The success or otherwise of the Bill depended very largely on the support and loyalty of the producer and the amount of wisdom he credited to those who were to be entrusted with the carrying out of the provisions of the Bill. (Hear, hear.) In a deliberate policy of State interference it was imperative that no undue restrictions were imposed, and no arbitrary powers placed in the hands of municipal authorities, which did not always possess sound and practical knowledge of the subject. If the authorities were to take a course which would make the production of milk more difficult or more costly he thought it would be unjust to the children of our great industrial centres. He did not mean that they should resist progress, but he meant that it was of great importance not to cause disturbance in the milk supply. (Hear, hear.) It was right to proceed cautiously, guided by common-sense and practical experience, not by force and theories.

He was entirely in sympathy with the view that they should have whole-time veterinary inspectors. (Hear, hear.) In regard to compensation, he was quite sure that to deal with the matter of compensation in a narrow and illiberal spirit would not advance, but would greatly retard, the influence of legislation. None of them were friends of the tuberculous cow, but they surely did not want anybody to make a present of that animal to the State. (Hear, hear.) If they did not give full compensation they would provoke obstruction, and he feared the result would not be entirely satisfactory. (Applause.)

Dr. G. H. GARRATT (Cheltenham) pointed out that the word "Inspectors" under the Order might have a complication of meanings. One hardly knew what it meant. It was a matter of regret that in an Order of the Board of Agriculture they should mix up this word "Inspector." One sort of inspector was referred to in

connection with notification, and then there was the veterinary inspector: they should have called him the veterinary officer. However, that was a minor point. He was absolutely at one with Dr. Fremantle in recognising that they should all work together, and that if the thing was to be a success that must be so. (Hear, hear.) It was of great importance when there was any disagreement in any great public health department with regard to the appointment of a veterinary officer, he recognised it was a misfortune that a local council should appoint him, and especially in rural councils. Without security of tenure, that condition had been so unfortunate with regard to medical officers of health in that they could not be sufficiently independent. (Hear, hear.) They had to deal with farmers and other interested persons whom they came in contact with as members of the Council. That was not desirable unless they were independent. (Hear, hear.) He was quite sure that the veterinary inspector, as well as the medical officer of health, must have security of tenure. This Bill was very much wanted. As medical officers of health they saw the great desirability of such a Bill, particularly with regard to registration; the registration of dairies and milk shops in a town of any size was of immense importance. In Exeter, for instance, there would be some milk shops which ought to be registered in perpetuity in order to be kept purely sanitary; that was the case in every town. There was no power to prevent the occupiers of little shops who wanted to add two or three shillings a week to their income by the sale of milk, becoming milk sellers. It was one of the best provisions of the Bill that there should be registration or licensing annually, the license being given only to a suitable place and revoked if necessary. These things were of vital importance, and it was absolutely essential that medical officers and veterinary officers, and sanitary officers should all work together. He should say that the sanitary officer was the best to deal with the building, as he was best up in building construction, and he could write out the best notice giving details of the requirements. With regard to registration and licensing that would probably be for the sanitary officer and the medical officer of health to see to, but as to the condition of the cattle, the veterinary inspector's services would be paramount, whilst as to the condition of the milk the services of the medical officer and the veterinary inspector would both be required. The duties were bound up together and could not be separated anywhere, and therefore they would all have to work together very heartily. (Applause.)

Mr. G. P. MALE said he had been extremely pleased to hear the graceful way in which the President's address had been referred to by Dr. Fremantle and Dr. Garratt, which augured well for the future carrying out of this Milk and Dairies Bill. He felt certain that it could not be carried out properly unless there was co-operation between the veterinary surgeons and the medical officers of health. The Bill was not quite clear as to the exact position of the veterinary surgeon and the medical officer of health in regard to the inspection of cattle, and certainly some alteration should be made in the clause referred to by Mr. Ascott (Clause 2), in which power was given to the medical officer of health to inspect cattle if accompanied by a veterinary surgeon. (Hear, hear.) The medical officer has the power to inspect the cattle. He (the speaker) was sure the medical officer would be the last to wish to go round and examine the cows' udders and give an expert opinion. The Bill should be made more clear on that point. (Hear, hear.) He thought the Local Government Board had accepted an amendment by the Royal College of Veterinary Surgeons that it should be made perfectly plain that the veterinary officer inspects the cattle, and that his report should accompany that of the medical officer of health. Mr. Ascott seemed rather nervous

that the Bill would not be carried out in small rural areas. He (the speaker) thought there would not be much difficulty about that, the district councils carried out the provisions of this Bill, and the dairies have to be registered, so that they must be inspected before they were registered, and the Act must be put in force in that way. Then provision was made in the Bill for the County Council to take on the duties where the rural district councils had not carried them out. Of course, the proceedings must be gradual, and the dairyman must be given time in which to set his house in order. There was a useful clause in the Bill which allowed the landlords, under certain conditions, to pay the cost of such structural alterations as were necessary. He (the speaker) did not know whether the Tuberculosis Order and the Milk and Dairies Act would work as smoothly together as had been anticipated. He thought that possibly there might be some overlapping. Personally he thought it would have been better if the veterinary inspector under the Tuberculosis Order was also the inspector under the Milk and Dairies Bill. Any veterinary surgeon, according to the Bill, might be called in by the medical officer of health. He could go to a certain length in tracing a tuberculous animal, but he was not allowed to apply the tests, and he was not allowed to slaughter the cow. If he was not an inspector under the Tuberculosis Order an inspector would have to be called in. He (the speaker) did not know whether the inspector had to make the diagnosis over again, or whether he was to accept the first diagnosis. The veterinary inspector under the Tuberculosis Order was responsible to the County Council or the borough council, whereas the district councils would be responsible for this Bill when it became an Act. (Hear, hear). They had had a realistic description of the condition of some of the cowsheds. He hoped they were not as bad as the speakers made them out. (Voices: "Worse.") He noticed that a good many of his audience were from the South-West of England. He must say, in all fairness, that in the district he came from they did not see the bad condition which had been described here. He was sorry to hear it was even worse than that. He must say that farmers had not been averse to well-considered regulations for the inspection of their dairies and their cows, so long as the regulations were carried out in a moderate spirit and were made to apply all over England. Before now they had had scattered Acts of Parliament which had been very drastic in certain districts, whereas other districts were allowed to go free, and now that they had, or were about to have, a Bill which they had asked for for a long time, he was sure they would all fall into line and carry out the spirit of the Act, if not the letter. (Hear, hear).

Mr. DUNSTAN (Holsworthy) observed that the subject under discussion seemed to him to be a somewhat nebulous one. He thought it was the same relation to the various Acts of Parliament as one of the component bodies does to that galaxy of stars known as the milky way. (Laughter). He did not think that there was the least likelihood of the Milk and Dairies Bill being considered this session, nor even next session. There was such an enormous amount of work before Parliament at present that such things as these had to slide. In fact, if one might prophesy the result of next year's legislation, the first would be Home Rule, the second Disestablishment, and the third something else: if they looked down the list at the "also ran's" they would find the Milk and Dairies Bill. (Laughter). The Bill had received the serious consideration of the Subcommittee of the Committee of the Royal College of Veterinary Surgeons. The interests of the profession had been considered and they would be submitted to Parliament when the time came. They need not fear but that their interests would be thoroughly looked after.

There appeared to be great trepidation in the minds of some people that there was going to be a good deal of friction between the medical officer of health and the veterinary officer. Personally, he did not see why this should be at all. If each stuck to his own sphere of work there was no reason why one should encroach on the other. Nobody would deny that the medical officer should give the final word as to what was fit for the food of man. But they would not care for the medical officer to come among their pigs and say what food was suitable for them. Least of all should he diagnose the disease and say whether it existed or not. All he could say was whether it was food fit for the consumption of man. One speaker had wondered whether Mr. Ascott was exaggerating as to the condition of the cowsheds in this part of England. He (the speaker) said emphatically not. He thought Mr. Ascott had drawn it rather mildly. Those who were in the habit of going constantly among cows would see the absolute necessity of something being done to ensure greater cleanliness than at present existed in the cowsheds. There was no food, he was sure, produced under filthier conditions than milk. There was great need for something being done. (Hear, hear).

Mr. J. A. DIXON (Leeds) observed that from all accounts the cowsheds in the south-west of England were in a bad condition. It would probably be news to gentlemen in the south that in the rural parts in the North no words could exaggerate the filthy and unsatisfactory condition of the cowsheds. Long observation of these holes of filth led him to think that annual licensing was required by law, under strict conditions. Why should the farmer be molly-coddled, and dry-nursed, and coaxed and persuaded, and rewarded with something in the way of compensation? As a matter of expediency he would admit that at present it was almost essential to grant some compensation for the destruction of cows, but on principle he would not give the farmer a farthing. It was thirty-eight years since the Public Health Act came into force. During that time those who sold meat, and bread and other things had been looked after by the law. After thirty-eight years working of the Public Health Act they were going to reward the farmer for declining to sell a tuberculous animal. If a butcher was found with diseased meat on his premises he was liable to three months' imprisonment. He was not rewarded for being good, and not dishonest to the general public. Why should the farmer? He (the speaker) saw scores of cows go up for sale with tuberculous udders. They came to his place from Scotland and from all the dairying districts of the North with huge tuberculous udders. How many hundreds of children consumed the milk of these cows? Should the farmers be rewarded for having such cows destroyed? He said, No. The farmer should be given six months (laughter). Mr. McIntosh had remarked that harsh measures would lead to obstruction of the Bill. Let the farmers resist it. Their opposition must be broken down. If they would not do the right thing in the ordinary way, they must be made to do it. The Milk and Dairies Bill and the Tuberculosis Order would to a large extent overlap, but he rather thought when the Bill came into operation—if many of them should live to see it—it would be found that the officers working under the Milk and Dairies Act would do the work under the Tuberculosis Order, and would come in and clear up the debris.

Mr. ASCOTT, in reply, said he was grateful to the medical officers for their sympathetic references to the veterinary profession, and for the cordial way in which they had welcomed the veterinary surgeons' assistance, there was one point which he did not make clear, and that was that the farmer would object to anybody but the veterinary surgeon inspecting his cattle. That was a point that had been made at various meetings of

farmers. It was obviously the farmers point of view that he should have somebody who was an expert to examine his cattle. Another topic of discussion had been whether the expense should fall on the landlord or on the owner of the cow. Most of them were in favour of suavity as a mode of policy because of the great opposition which an opposite policy would entail in the West. He was sorry to hear that the cowsheds were as bad in the North as they were in the West. He thought the trouble was not so acute in the North where the milk industry had not so many small holders as in the West, but apparently it was so. He had pointed out that many of these buildings were unsuitable and would have to be reconstructed, involving a large expenditure in the first instance. He agreed that they should help these farmers and dairymen to do the best for themselves and for the community in general.

SOUTH DURHAM AND NORTH YORKSHIRE VETERINARY MEDICAL ASSOCIATION.

The third annual excursion took place on Friday July 11th, and like the two previous outings proved an unqualified success, and a merry party of members and their friends to the number of thirty-three, left Darlington by motor char-a-brac for Wensleydale, bent on a good day's enjoyment, with a resolve to leave all care and worry of business behind for one day in the year at least.

Joining the Great North Road about seven miles from Darlington, the village of Catterick was the first place of interest passed. This was a flourishing city in the time of the Saxons, and here the marriage of King Ethelred with the daughter of Offa, King of the Mercians was celebrated. It was destroyed during Danish outrages, and never regained its former greatness.

Leaving Catterick the journey was made by way of Hornby Park, the seat of the Duke of Leeds, to Leyburn, a distance of twenty-four miles from home, where the party were quite ready to do ample justice to an excellent lunch provided at the Golden Lion Hotel.

After lunch some of the energetic ones had a walk along the famous terrace of rock known as Leyburn "Shawl," and were fully repaid, for here the view is superb. Immediately below is the river Ure winding boldly through the dale, and in front a wooded steep, crowned by the height of Pen Hill. Others paid a visit to the antique shop of Messrs. Horne and Sons, where many interesting curios were inspected.

The ladies appeared to pay particular attention to old furniture, china, and clocks, but their persuasive powers had little avail upon their male companions, and it seemed as if that ear of the men next the lady had become suddenly hard of hearing when the prices of the articles fancied were named.

The journey was now resumed to Aysgarth Falls, 10 miles distant from Leyburn, and pleasant as had been the journey to Leyburn it was surpassed by the surroundings now passed. The sun shone down from an almost cloudless sky, the high hills were clearly marked out, hay making was in full swing, and those so employed gave us a friendly cheer as we passed quickly on.

Next we passed through Redmire, and one mile from here is Bolton Castle with massive walls which have stood for nearly 700 years. This ancient stronghold is chiefly memorable as having held as prisoner Mary Queen of Scots, and the room in which she was kept is shown to visitors.

On reaching Aysgarth Falls the more active ones climbed the rocks and walked on to the village, when a good old-fashioned tea, such as can only be obtained in Yorkshire, was partaken of.

The return journey was made along the opposite side of the river to that we had previously passed along, and Leyburn was soon reached. Here we altered our journey home and went by way of Richmond, arriving back to Darlington at 8.30, in ample time for some of the members to catch their trains home.

Before breaking up three hearty cheers were given to the chauffeur, in whose capable hands all had felt perfectly safe.

J. H. TAYLOR, Hon. Sec.

ANNUAL DINNER OF THE NATIONAL VETERINARY MEDICAL ASSOCIATION.

The annual dinner of the Association, the first under the new régime, was held at the Trocadero on Tuesday evening, Mr. W. Hunting, President, occupied the Chair. Nearly a hundred members and guests were present, amongst whom* were Sir John and Lady M'Fadyean, Mr. J. H. Carter, President of the Royal College of Veterinary Surgeons, Miss Hunting, Miss Carter, Maj.-General F. Smith, C.B., Mr. Thomas McRow, R.A.S.E., Mr. J. Abson, Mr. N. Almond, Mr. and Mrs. Hugh Begg, Mr. and Mrs. C. Blackhurst, Mr. J. W. Brittlebank, Mr. Fred Bullock (Secretary, R.C.V.S.), Mr. J. B. Buxton, Mr. and Mrs. W. S. Carless, Mr. W. Roger Clarke, Mr. D. Gladstone Davies, Mr. and Mrs. Davis, Prof. J. Dunstan, Mr. R. J. Foreman, Mr. W. J. Foreman, Mr. H. Gray, Mr. F. W. Garnett, J.P., Mr. W. L. Harrison, Prof. F. Hobday, Mr. P. J. Howard, Mr. R. Hughes, Mr. Fred Hunting, Mr. R. C. Irving, Mr. Alexander Lawson, Mr. G. H. Locke, Mr. J. W. McIntosh, Mr. G. P. Male, Mr. H. A. MacCormack, Mr. P. J. Mullane, Mr. and Mrs. C. Pack, Capt. Rees-Mogg, Prof. E. Brayley Reynolds, Mr. and Mrs. S. H. Slocock, Mr. P. J. Simpson, Mr. and Mrs. F. G. Samson, Mr. T. C. Toope, Mr. George Thatcher (Solicitor, R.C.V.S.), Prof. G. H. Wooldridge, Mr. J. Willett, and Mr. W. Woods.

Sir JOHN M'FADYEAN, in proposing "The United Services," paid a tribute to the Navy, Army, and Territorial Forces. The Navy, he said, had glorious traditions behind it, and the only fault apparently that could be found, even by Continental critics, with the Army was its smallness.

Capt. REES-MOGG, in responding, referred to the work done by Major-General Smith, especially during the time he was Director-General of the A.V.D. He was sorry the Army Veterinary Department was not better represented at the dinner, and he expressed the hope that parents would see the advantage of their sons going into the Army, because although diseases in animals were becoming extinct in this country, members of the Army Veterinary Department had an opportunity in other countries of coming into contact with all the diseases under the sun.

Mr. McRow (Secretary of the R.A.S.E.) proposed "The Royal College of Veterinary Surgeons," and said there had been a great advance in veterinary science since the Charter was obtained by the R.C.V.S. He did not take a gloomy view of the future of the profession, because, although the horse seemed to be disappearing, other animals continued to flourish, and as years went on, the services of veterinary surgeons would be required as much as ever they had been. The intelligent owners of live stock to-day were more ready to take the advice of the veterinary surgeon than they had been in the past. He was connected with an Institution which had had a very close connection with veterinary science for many years, and, having regard to the great impor-

* A complete list was not available.

tance of the veterinary practitioner to the breeder of live stock, he believed that connection would long continue. Veterinary science had dealt in the past with a great many diseases, especially cattle plague and pleuropneumonia. He was old enough to remember Mr. Simonds, who went to Russia in connection with the cattle plague, and he had lived sufficiently long to see Sir John McFadyean going to India in connection with foot-and-mouth disease. In conclusion, he said he yielded to no man in sincere appreciation of the Royal College of Veterinary Surgeons, and he coupled with the toast the name of its President, Mr. J. H. Carter.

Mr. CARTER, in responding, referred to the valuable aid rendered to the College by its Secretary, Mr. Bullock, who had done, and was doing, a great deal for the College, and thus for the benefit of the profession. He thought no profession had made more rapid advance in the last decade than the veterinary profession, and that was all the more creditable when it was remembered that that advance had been made without outside aid. A little more help from Government would be appreciated. Veterinary surgeons had every reason to be proud of their profession, although small it was progressive. Unfortunately the College was wretchedly poor financially, as was shown at the last Council meeting, when the Treasurer explained that the liabilities were £227, and the assets only £27. Unfortunately, at present, students were falling off, the reduction during the last year amounting to 34 per cent. Consequently there was one-third less revenue now than there was seven years ago. It had been said that the Council of the R.C.V.S. was an ornamental Council, but as a matter of fact it was a hard-working body. During the last year it had been very busy. The whole of the Byelaws had been revised, and in no case had the revision involved the introduction of any question of principle. A special Committee had been appointed to revise the Regulations governing the Fellowship Degree, and to draw up regulations for the institution of a new Post-graduate Diploma in Veterinary State Medicine, for which a new Supplementary Charter would be needed, and steps would shortly be taken in that direction. The Registration Committee, which was composed of the whole of the Council, had been occupied in considering cases of unprofessional conduct on the part of members, and also of the illegal use of the title of "Veterinary Surgeon" by unqualified men. During the last twelve months over 80 cases had been dealt with; prosecutions were instituted in eleven cases, and convictions obtained in ten, only one case being dismissed. The Parliamentary Committee had had under consideration many Public and Private Bills affecting professional interests, and under the energetic Chairmanship of Mr. Garnett, had closely watched all matters that might interfere with the rights of the profession. There were two Bills especially, the Milk and Dairies Bill and the Milk and Dairies (Scotland) Bill, and certain amendments had made it clear that any inspection of cattle must be conducted by qualified veterinary surgeons only. He was pleased to see that the Dogs Protection Bill had been thrown out. Mr. Garnett and the Secretary gave evidence on behalf of the College before the Departmental Committee on the Public Veterinary Services, and the Committee had made certain recommendations, amongst them being that students possessing a suitable science degree should be granted exemption of one year in the four years necessary to qualify as a veterinary surgeon; that twelve scholarships should be offered each year of an annual value of £80 tenable at a Veterinary College for three years; and that scholarships of an annual value of not less than £100 and not exceeding £150 should be offered each year to enable qualified veterinary surgeons to undertake advance study and laboratory work at suitable institutions. The veterinary profession was

not yet dead—in spite of the advent of motor traction. In 1911 there were in Great Britain 1,500,000 horses, 26,000,000 sheep, 7,000,000 cattle, 3,000,000 pigs and 2,000,000 dogs, the total number of these animals being nearly equal to the human population of the British Isles. Those figures showed that there was plenty of work for the veterinary surgeon, and he thought there never was a brighter prospect for the profession than there was at the present time. In conclusion he alluded with regret to the fact that during the last twelve months the profession had lost four Past-Presidents of the National Association, Mr. Bower, Mr. Hedley, Mr. Faulkner, and Mr. Roberts, and two other old members, Mr. McGavin and Col. Steele. Every veterinary surgeon regretted their loss and the Association was the poorer by their deaths.

Dr. McCALL proposed "The National Veterinary Medical Association." He said the Association had done a very good work for the veterinary profession in the country for a great number of years, and now that the Veterinary Societies were affiliated with the Association he was sure it would do even better work than it had done in the past. There was one point he wished particularly to direct attention to, and that was the advisability of the younger men coming forward. During all the years he had attended the meetings of the Association it had been very seldom his privilege to hear a paper from a young member of the profession, most of the papers having been read by old and experienced members. He thought it was time that state of affairs was altered, and that the younger men came forward. It was, however, very difficult to obtain new recruits for that purpose, owing partly to the fact that they were subjected to a very strong fire of criticism, and he had come to believe that if the Association was to continue to do the good it had done in the past there ought to be a law that the discussions should be of a more friendly nature, and men who criticised a paper ought to look lightly at its faults, and give the reader more credit for the strong points.

The PRESIDENT, in rising to respond, was received with great cheering and musical honours. He agreed with Prof. McCall that the younger men did not take a more prominent position in the Society, but he did not agree that it was because they were afraid of criticism. He would not give much for a man who was afraid of being criticised. There was an old friend of his who was supposed at the Central Veterinary Medical Society to put the fear of God into every man who read a paper there, but that gentlemen had never put any fear into him. He joined with Prof. McCall in asking the young men to come forward and take their proper share in the burden of the Association. It was the thirty-first gathering of the Association and he wanted to claim for it that during those 31 years it had contributed a good deal to veterinary knowledge, not only in original work, but in correcting many erroneous opinions.

Alluding to the International Veterinary Congress to be held next year, he said it had been decided by the Association to take a part in that Congress and only to hold a formal meeting of the Association so as not to conflict with the Congress meetings. He paid a tribute to officers of the Association, without whom he considered the Presidents would make a very poor show; in fact he declared that Mr. Harrison was the man who really ought to have the chief credit for running the meeting this year, and all the credit for the dinner. (Hear, hear.) That was probably all the reward he would get. (Laughter.)

Mr. T. C. TOOPE proposed the toast of "The Guests," this was responded to by Mr. George Thatcher.

Prof. WOOLDRIDGE proposed "The Ladies," and in the course of his remarks suggested that the ladies of any locality in which the National Association met should band themselves together to entertain the

lady visitors when the men were engaged in the meetings.

Mr. FRED BULLOCK (Secretary R.C.V.S.) in returning thanks on behalf of the ladies, humorously expressed their gratitude for the hearty manner in which the toast had been proposed and received. He emphasised the necessity in these days of ladies themselves replying to the toast, and he asked the officials in future to place a lady's name on the list to reply for her own sex.

DRUGS AND INSTRUMENTS.

There was the customary display in connection with the meetings of the National Society, in the Library of the Royal Society of Arts—a good room, well lighted, and conveniently situated on the ground floor, facing the entrance, and it was visited by a good percentage of the members present at the meetings.

Messrs. WILLOWS, FRANCIS, BUTLER, and THOMPSON had, as usual, a well displayed stand, showing most of their new familiar preparations. One of the recent additions is "Vermifugen" for dog practice. It contains Santonin and Chenopodium, and is put up in liquid and in capsules. Other preparations on show were Black-leg vaccine, which steadily increases in favour: Gelatine-coated horse balls; Iodotan (iodine and tannic acid); Formogen—a small pocket lamp for use in formaldehyde disinfection of stables, etc.; and Arsenical tablets for internal parasites in sheep.

Messrs. C. J. HEWLETT & SON were showing their "Unique" horse balls; "Magnum" pessaries in nine prescriptions, a full series of soluble tablets ("Soltabs") hydrg. perchlor. et biniod.—these are made to a number of prescriptions; "Paraphroxia," analgesic and cathartic. "Curex," a non-greasy cream for eczema and irritable skins in dogs and cats; "Pelletiernine," a vermifuge for sheep and lambs, stated to give excellent results; "Antiseptigen," (poison) a liquid antiseptic and resolvent, of use for splints, curbs, capped elbows, etc. Recent additions are their Super-lactique teat bougies, made the size and thickness of a milk syphon, and with a fine cord running through each, so that the undissolved portion may be removed as required, useful for injured teats, or after operating on a blind teat; and their "Special green blister." They were also showing milk fever outfits (metal cylinder), hypodermic syringes, etc., in several convenient forms.

Messrs. HUISH & Co., of 12 Red Lion Square, London, exhibited in addition to their usual good display of Veterinary Instruments, the necessary equipment for Veterinary Inspectors, including a fine Microscope, Water and Hand Centrifuges, Micro Slides of Milk Smears showing Tubercle, and the parasites of various animals. Pasteur Vaccines and Sera, Blacklegine, Vergotinine (the successful remedy for broken wind), Beach's Thermo Cautey, The Massagette (for rubbing in lotions, etc.), and other specialities.

Messrs. PARKE, DAVIS & Co. showed, besides most of their standard preparations, the recently introduced "Phylacogens" for veterinary use, described as "sterile aqueous solutions of metabolic substances generated by bacteria grown in artificial media: the bacteria-free filtrate containing suitable preservatives constitutes the phylacogen." The process was originated by Dr. A. F. Schafer (California). The two which have been tested are Pneumonia phylacogen and Mixed infection phylacogen, and satisfactory tests are reported. Also canine distemper vaccine, prophylactic, in sets of three bulbs; and curative, in sets of six bulbs. The prophylactic is a polyvalent vaccine prepared from several strains of *B. bronchosepticus*. The curative contains,

in addition, cultures of *Staph. albus* and *aureus*, *Strept. pyogenes* of canine origin. Formidine: a powerful antiseptic, for internal or external use, "more effective than iodoform and almost odourless. It may be used as a dusting powder, moist gauze or ointment: and internally as an intestinal antiseptic in conditions depending on infection or fermentation." It is stated to contain 56 per cent. iodine, with condensation products of salicylic acid and formaldehyde: and to have stood the test of delicate operations in human surgery.

Messrs. BURROUGHS, WELLCOME, & Co. were showing a series of veterinary sera and vaccines, as well as numerous other preparations, including Tuberculin, Mallein, Tetanus antitoxic serum (veterinary); Anti-colon-bacillus (canine), Anti-streptococcus serum, Pyogenes (canine); Anti-streptococcus serum, Strangles; and a series of vaccines. Also a large selection of "Tabloids."

Messrs. ARNOLD & SONS had a fine show of instruments, most of which are known in the profession. One of the more recent additions is a Milk Fever Syringe, all metal, the rubber pump being replaced by a metal syringe with a metal piston, and metal tubing—the whole of the apparatus can be boiled. Another was the Tattooing apparatus for use on the gums of horses, as in use at Aldershot; and a third a powerful Castrating instrument for use on bulls—an Italian suggestion—by which the dependent scrotum with the testicles are removed together by means of a pair of fine crushing edges with powerful levers.

THE ANGLO-AMERICAN PHARMACEUTICAL Co., LTD., handling Huxley's Pharmaceutical Products, make a feature of putting up certain of their numerous preparations with the name and address of the customer on the label; one of these, a medicated shampoo powder for canines, might prove popular in some directions. Their chief item to-day is Huxley's antiseptic plasma dressing, for treating inflammation, congestion and wound surgery in animals. This also is put up without maker's name. They issue an illustrated list, and their address is 59 Dingwall Road, Croydon.

Royal College of Veterinary Surgeons.

EXAMINATIONS IN EDINBURGH.

At the Examinations in Edinburgh held on July 12th, the following gentlemen passed their Final Examination, and were registered members of the R.C.V.S.;—

Mr. James Conner.
Mr. Ronald Scott Little.

Veterinary Carbolic Oil.

Carbolic oil, veterinary or other, should be made with the crystallized carbolic acid. A clear solution is always obtained in this way.

If the liquefied carbolic acid is used, the product is not only opaque and requires to be shaken before use, but the strength of the carbolic oil made with it is lower, since the liquefied carbolic acid contains only 90 parts of phenol in 99. Doubtless it is often made with the liquefied acid for convenience, but it is not right to do so, even if the strength is made up. The fact that stock labels recommend the bottle to be shaken is nothing to go by.—*Pharmaceutical Journal*.

DOGS BILL.

The Committee met again on July 23rd and decided not to proceed with the Bill, in view of the deadlock reached at the meeting on July 16th and of the advice given by the Speaker, who had been consulted on the situation.

The Suggested Cattle Testing Station in Scotland.

Mr. Runciman attended a meeting of Scottish cattle breeders in the Highland and Agricultural Showyard, Paisley, to discuss the question of establishing in Scotland a cattle testing station on the lines of that being established at Pirbright, in Surrey. Opinion north of the Tweed is sharply divided on the point, the breeders of Ayrshire cattle having ranged themselves in strong opposition to the movement. The attitude of the south-western counties is difficult to reconcile with the keen business instincts of the farmers of that district, as it implies a short-sighted view of the situation and defective appreciation of the issues involved. There are certain drawbacks to the proposition, the chief of which is the risk of contamination associated with the bringing together for a stated period of animals from widely separated areas: but the dangers are no greater to Ayrshire than to other cattle, and it would be unfortunate if the expected benefits were to be denied to the supporters of other breeds merely to palliate exaggerated ideas of the disadvantages in one district.

Mr. Runciman, in a careful review of the situation, met the objections effectively. He set aside the question of expense with the remark that, although the cost of quarantine might be high in proportion to the ave-

rage price of an Ayrshire, the latter was rising steadily, and the upward movement would be accelerated by the security which the testing station would give to the buyer. He had more sympathy with the suggestion of risk from infectious disease, but he did not think they need worry very much about the danger regarding foot-and-mouth disease, and in any case owners of the lower-priced Ayrshires incurred a smaller risk than breeders of Shorthorns and other animals of higher value. The President of the Board of Agriculture hoped that the breeders of Ayrshires would reconsider their position in the light not only of tuberculosis, but all other diseases which might affect their opportunities when they went abroad. He was not a partisan for or against testing stations, and in whatever course he should take he would be actuated only by a desire to help the export trade of both Scotland and England.—*The Times*.

Tuberculosis in France—Notification.

At Tuesday's sitting of the Academy of Medicine the motion of Dr. Roux, Director of the Pasteur Institute, to recommend the Government to make the notification of tuberculosis compulsory, was finally adopted by a large majority. The motion declared that it was in the interests of the public that every case of recognized tuberculosis should be compulsorily notified so soon as the diagnosis was established. It insisted that the notification to be made to the sanitary officer should be regarded as a professional secret and that the authorities should undertake, once notification has been made, to provide assistance both for the diseased persons and for their families, if necessitous.

It is estimated that nearly one-seventh of the deaths in France are due to this scourge.—*The Times*.

The Jewish Method of Slaughtering.

It may be recalled that a Shochet at Halifax was recently convicted for killing an animal according to the Jewish rites, and thus, it was alleged, causing it unnecessary pain and suffering. An appeal was thereupon lodged, and the result has been the squashing of the conviction by the High Court on the ground that Shechita is not more cruel than other methods of slaughter. We would go further and say, unhesitatingly, that it is positively far less cruel and infinitely less brutal. Against the windy declamation of anti-Shechita enthusiasts may now be set the considered judgment of an important Canadian Court. This is a development worth obtaining. It is significant that places so far apart and widely divergent in character as Nova Scotia and Finland should within a few weeks have stamped upon the mischievous anti-Shechita agitation.—*Jewish Chronicle*.

Proposed Veterinary Department for Edinburgh.

It was agreed at a meeting of the Public Health Committee of Edinburgh Town Council on Tuesday, July 20th, to remit to a joint committee of the Public Health and Markets Committees a motion by Councillor Bruce Lindsay as to the desirability of setting up a separate veterinary department for the city under a duly qualified veterinary inspector, and of transferring to said department the veterinary inspectors at present in the medical officer of health's department. A letter from Mr. A. M. Trotter, Association of Veterinary Officers of Health, Glasgow, with reference to the advisability of creating a veterinary department to deal with the supervision of the meat and milk supply of the city was similarly dealt with.—*N.B.A.*

Lieut. T. W. Lloyd to be Capt. Dated July 3.

Personal.

The Corporation of London have consented to Mr. T. DUNLOP YOUNG, M.R.C.V.S., visiting the chilled beef and frozen meat establishments of Argentina at the request of the Argentine Government. With reliable knowledge of all the facts—economic, scientific, and commercial—before them, we believe that the question of the re-admission of Argentine cattle to this country will assume a totally different aspect from that it now presents.—*Meat Trades' Journal*.

OBITUARY

WILLIAM MARK REEMAN, M.R.C.V.S., Bury St. Edmunds
Graduated, Lond: 1887.

Mr. Reeman died on Sunday, July 20th, from pneumonia. Aged 51 years.

SIR RICHARD POWELL COOPER, Bart., M.R.C.V.S., Queen's
Own Royal Yeomanry Cavalry, Lichfield.
Graduated, Lond: April, 1868.

We regret to have to announce the death, which occurred on Wednesday, July 30, at Berkhamsted

from double pneumonia, of Sir Richard Powell Cooper, of Shenstone. He attended the Staffordshire Agricultural Show at Wolverhampton last Wednesday, and introduced a deputation from Lichfield asking that next year's exhibition should be held there." He then caught a chill, but the next day left Lichfield for Berkhamsted. On arrival at Berkhamsted, however, he was taken seriously ill and proceeded to White Hill, the residence of his son-in-law, Major R. M. Foot, where he died. Sir Richard, who was born in 1847, was the only child of Mr. Henry Cooper, of Clunbury, Aston-on-Clun, Shropshire. He was a member of the firm of Messrs. Cooper and Nephews, chemical manufacturers and exporters of pedigree live stock.

Sir Richard Cooper had large agricultural interests. He farmed over 2,000 acres of his own land in England, mostly in Staffordshire, where he had his chief residence at Shenstone Court, Lichfield, but he also owned great possessions in land and livestock in almost every continent—in Australia, South Africa, Russia, the Argentine, and Paraguay. At Shenstone he kept a large herd of pure-bred Shorthorn cattle, as well as crossbred stock, a famous flock of Shropshire sheep, and large black Berkshire and Yorkshire pigs. His farms were managed on sound business principles, crop production and stock-raising being adjusted on the system of mixed farming that constitutes the highest form of economic husbandry.

It was his enterprises in the opening up of new countries that made Sir Richard Cooper so prominent in the work of making known abroad the qualities of British breeds for improving the native types. One of the keenest and shrewdest business men of his time, he was constantly on the look-out for new markets for our highly-bred stock, and Sir Richard had an intense love of country pursuits, not as hobbies merely, for he was a firm believer in the doctrine that all things of a commercial nature should be made to pay. The amount and value of his public work will probably never be known, for he shunned publicity. It is an open secret that it was he who came to the rescue of the Royal Agricultural Society, a body of which he had long been a council member, when the Park Royal venture failed, with a guarantee to bear any loss incurred in the first few years if the migratory show system were resumed. The resumption of the prize farm competitions was also due to his generosity in providing the prizes until the Society was in a position to take over the full responsibility. In other ways his tireless energy, shrewd initiative, and generosity were given freely and always with advantage to the cause of agriculture.

Sir Richard married, in 1872, Elizabeth Anne, who survives him, daughter of Mr. Elias Ashmole Ashmall, of Hammerwich, Lichfield. His elder son, Richard Ashmole, who succeeds to the baronetcy, is the member for Walsall; Sir Richard also leaves another son, William Francis, and three daughters.

The funeral will take place at Berkhamsted Parish Church on Saturday at 2 p.m., leaving White Hill at 1.45 p.m.—*The Times*.

VETERINARY INSPECTORS.

Sir,

At the present moment there seems to be some doubt as to who should be inspectors under the Tuberculosis Act. Allow me to inform all those who acted in the above capacity before the County Councils came into force that they become veterinary inspectors of the Council.

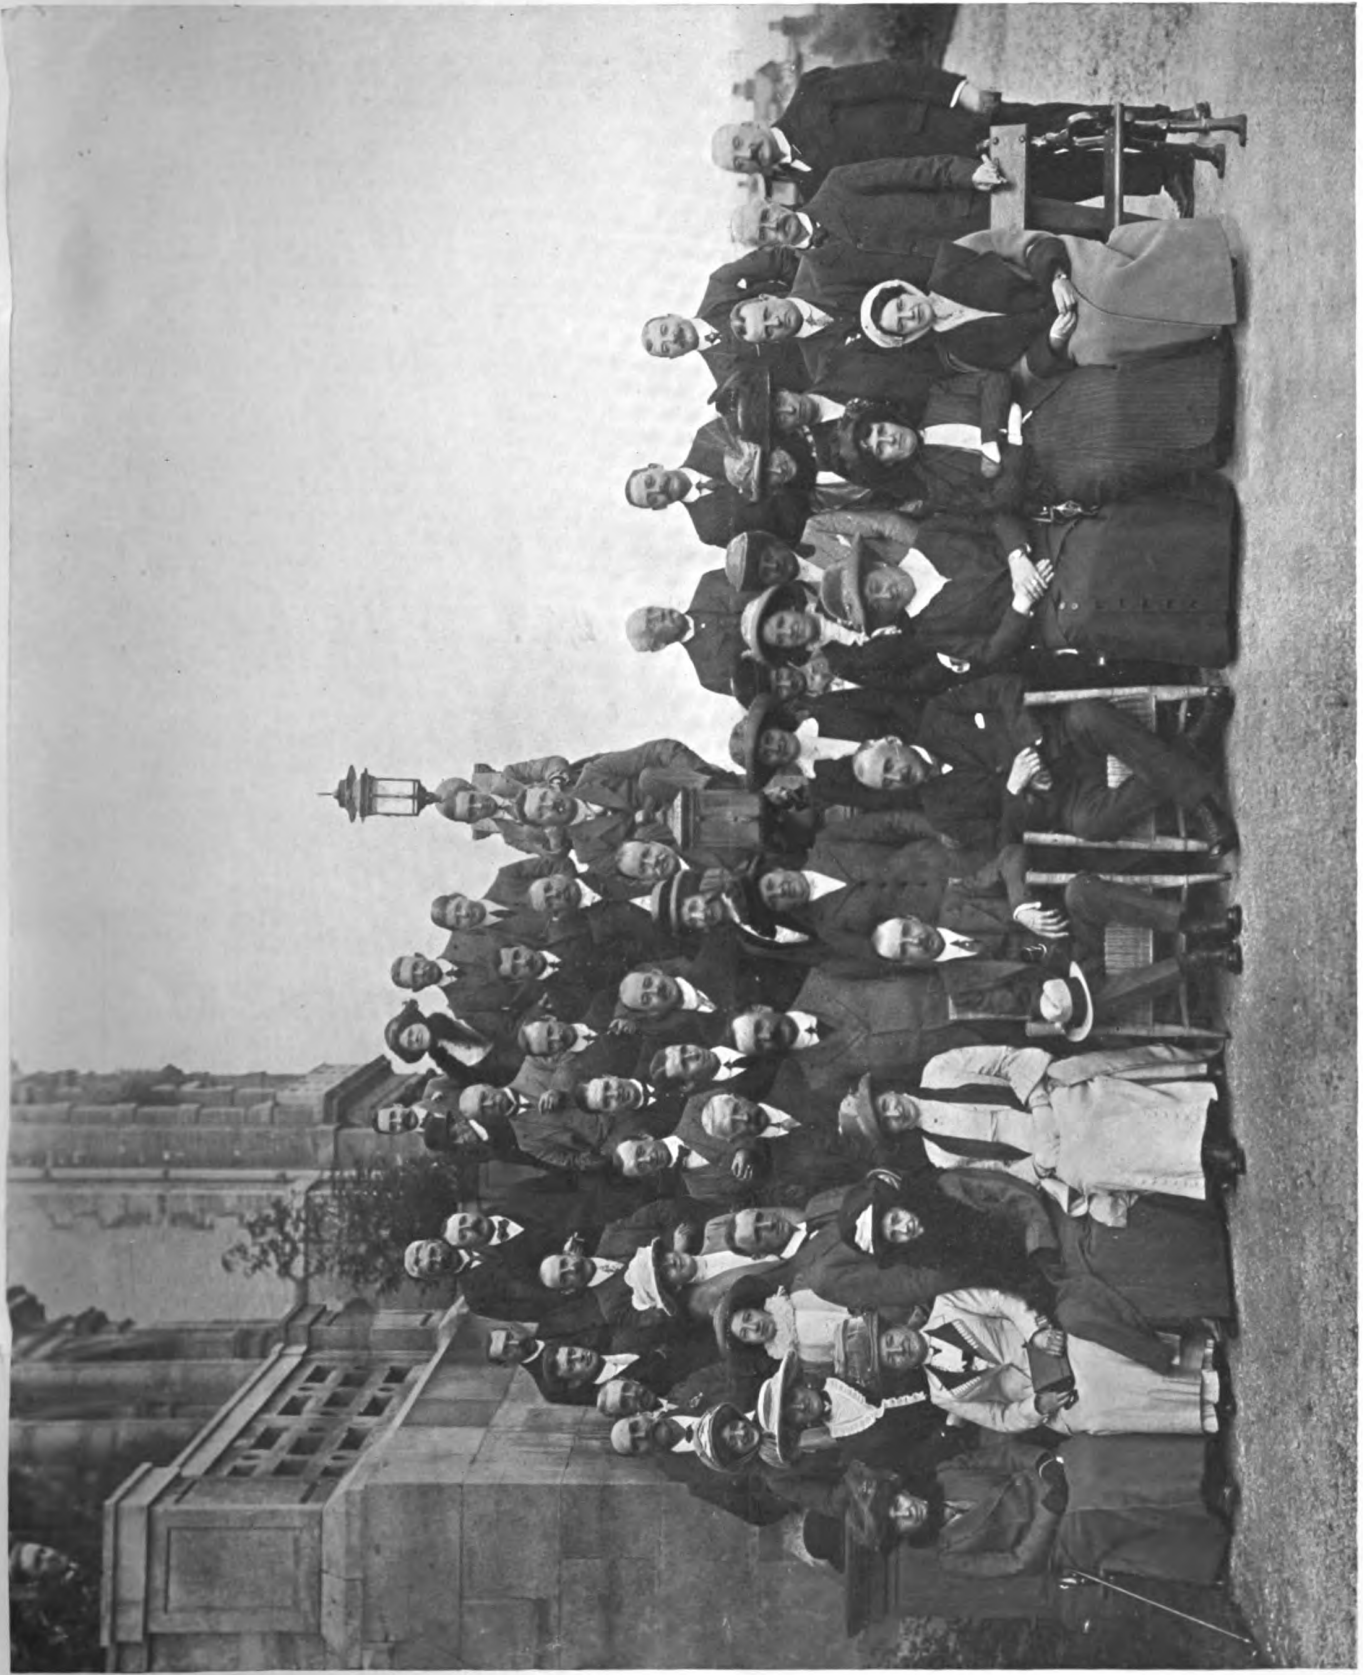

Should the Council consider any existing office unnecessary they will have power to abolish the office, but the officer will be entitled to compensation. All existing veterinary practitioners please note, especially "Scrutator."

—Yours truly,

July 28th.

EXISTING PRACTITIONER.

ABSTRACT

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1309.

AUGUST 9, 1913.

VOL. XXVI.

MILK FEVER.

Most of us can remember the days when the cause, the prevention, and especially the treatment of milk fever used to provide material for long and frequently recurring discussions. Hardly any animal disease gave rise to so much divergence of opinion, or was treated by such radically different methods. No real advance was made till the introduction of Schmidt's treatment; and, after that was once fairly established, milk fever began to take a much less prominent place in professional discussions than before. Schmidt seemed to have said the last word upon treatment; and the success of his method rendered prevention a much less important question than it had been. Yet we may still have a little to learn even as regards treatment—as, for instance, such points as the addition of adrenalin, which Mr. Wallis Hoare recommends, and which has also given good results upon the Continent. The discussion in our columns, initiated by Mr. Blackwell, shows clearly that we have something to learn as regards prevention.

The propositions put forward are all based upon clinical experience, and they reveal some differences of view. But, so far, there seems to be a general consensus of opinion against completely milking out soon after calving. This is not surprising in view of the success of Schmidt's method of distending the udder in milk fever, which naturally suggests some such procedure as that advocated by Mr. Blackwell as a preventative. That procedure seems to have much in its favour, but the experience of more than three or four men is necessary before its value can be judged. Again, Mr. Hoare calls attention to some well-known apparent contradictions in the incidence of milk fever which render it impossible to accept any method of prevention without most careful and extensive testing. There is another point which should be remembered in connection with apparent failures of Schmidt's treatment or any method of prevention, especially when they depend upon the evidence of laymen. Clinical records show that there are cases which closely resemble milk fever in their symptomatology, but in which the coma and paresis are due to quite other causes. Some of these cases may remain unrecognised, and thus help to confuse our ideas of milk fever, many of which are still vague and unsettled, the only method of improving them is the careful comparison of clinical experience.

Possibly no one practitioner may succeed in definitely establishing the cause of milk fever. But one practitioner devised a cure for it, and it is quite possible that others collectively may work out a satisfactory system of prevention.

THE PREVENTION AND TREATMENT OF MILK FEVER.

By E. WALLIS HOARE, F.R.C.V.S.

It might be imagined by some sections of the community that, owing to the marked success attending the modern treatment of milk fever, preventive measures would cease to be a subject of interest to the practitioner. This, however, is far from being the case, and we still seek to solve the problem of prevention, although the remedy is in our hands—a striking example of philanthropy, but one which we do not always get credit for.

In discussing the value or otherwise of methods of prevention, we must direct attention to certain points. In the first place, all practitioners must have observed the small number of cases of this disease that occur in some districts. It is not uncommon to find, on enquiry from the proprietors of large dairies in certain localities, that they rarely or never have a case of milk fever. Yet no precautions are taken—and the rules for prevention usually recognised are holdly transgressed—or it may happen that in a dairy in which for years no cases occurred, the proprietor becomes startled by having one or two animals affected, although no alterations were made in the *régime* or method of milking.

On the other hand we are equally well aware that, in spite of every means of prevention, cases will occur in some dairies.

The practice of leaving the calf with the cow for forty-eight hours is a very old method of prevention. It was advised by the late Prof. Williams, many years ago. That it fails in several instances we have abundant evidence to prove, and, moreover, there are certain drawbacks which cannot be ignored. It is well-known that when the calf is left with the cow for the period mentioned and then removed, the cow in many instances becomes very excited and bellows for long intervals; the complaint too is often made that she is difficult to milk, she "holds her milk," as the farmer says, and the calf does not readily take to the altered condition of feeding. However, this may be, I have now seen so many cases of the disease where this measure was adopted that I do not believe in its efficacy. I am the possessor of a very good cow which has had an attack of the disease in two consecutive years, although the above and every other preventive measures were adopted. It is a question too whether the calf can remove and use sufficient milk from the udder of a good milch cow, so as to prevent the evil effects of an accumulation of milk in the organ. Probably it may be said that in the case of a mare the foal is able to use up all the milk, but it must be

remembered that the cow is rendered more or less a milk-producing machine, and her natural conditions are altered to suit the needs of man.

From my observations on the disease I conclude that a method of prevention, which, at any rate seems to prove useful in many instances, is to avoid milking the cow dry for some days after calving. My instructions are, to milk her at intervals, but not to let the udder get too full. This I have found more effectual and more acceptable to the owners, than the plan of leaving the calf with the cow.

As regards any ill-effects from relieving a full udder prior to calving, I have never observed any; in fact, in the majority of cases of the disease I have met with, the udder had not been interfered with. Unless the organ is distended, I do not see any necessity for milking prior to calving. Experience of the disease under various conditions has taught me that many of the etiological dogmas laid down cannot be accepted. High condition, hot weather, etc., no doubt may act as predisposing causes, but when one meets with cases all through the winter months in cows whose condition is low, one is forced to be sceptical in this direction.

One factor, however, must receive due attention, viz., a large number of cases occur after the first milking, the initial staggering being observed very often at this period. But it must be admitted that cases occur at other periods; and it is then permissible to doubt the influence of the sudden emptying of the udder.

I have seen a case in which the symptoms presented themselves prior to calving, the animal going down in the afternoon, calving within twelve hours and still showing the usual symptoms. Treatment was adopted both before and after parturition, and was successful, but the animal did not get up until six hours after delivery.

Although the air treatment is so successful, yet certain cases will terminate fatally, and we know little or nothing with reference to the cause of death. No doubt some practitioners boldly assert that they *never* lose a case, just as they deny that any colt castrated by them could possibly die. This may be pure luck—or a bad memory.

I have observed that a small flabby udder, which is difficult to inflate, is an unfavourable sign. Relapses of milk fever are not uncommon, and I believe are due to early and complete milking after an apparent recovery, *plus* too much bulky food and exposure to hot sun. Attention to these details will often prevent a relapse.

In cases that are slow to get up, or in those where a second or third inflation of the udder fails to accomplish the desired effect, I have found that the hypodermic injection of adrenalin (1 to 1000) in doses of from 5ij. to 3iv., according to the size of the cow, proves very successful.

With reference to cases that occur some time after calving, we must admit a difficulty in the diagnosis in some instances. Although they yield to inflation of the udder, it must be remembered that chronic gastro-intestinal catarrh in cows after calving, is successfully treated by similar means. In this latter affection, nervous symptoms may occur,

and render a differential diagnosis by no means easy.

The simple inflation of the udder and its results in the disease mentioned is an object lesson in therapeutics. Schmidt deserves the highest honours that could be accorded to him by the veterinary profession and by stockowners, yet had he discovered some special bacillus in connection with the disease and failed in the successful treatment of it, no doubt he would have received more reward. It would be difficult to estimate the enormous saving in milch cows which has resulted from his discovery. In addition to this it suggests that simple measures may be discovered in the future for the successful treatment of diseases which at present fail to yield to "shot-gun" pharmacy. No doubt from a commercial aspect, so far as the practitioner is concerned, the ledger will not benefit to any extent, as thanks to the popular veterinary lecturer the majority of stock-owners in some districts have now added the milk fever outfit to their medicine chests, and only send for the veterinary surgeon when the case is going the wrong way. Too often he is called in to give the *coup de grâce*, and gets the credit when the case terminates fatally.

MILK FEVER IN COWS: SUGGESTIONS FOR PREVENTION.

I was on the point of recording a case of the above I had about three weeks ago, and it was with much pleasure and great interest that I read Mr. W. E. Blackwell's article in *The Veterinary Record* of July 19th, and again Mr. T. A. Huband's in the following number. Mr. Blackwell's communication recalls to mind an article I wrote in January, 1877, on Milk Fever in Cattle, which was published on February 1st of the same year in a paper called *The Practical Farmer*, issued by Messrs. Gouldings, of Dublin, and edited by a very old friend, the late Mr. J. S. Smithson. The article with a supplement, along with reports from several other members of the profession, was reproduced and recorded, with the proceedings of the tenth general meeting of the National Veterinary Association, held at Glasgow in August, 1892. Again, extracts from that paper were recorded in the first volume of my "Elementary Veterinary Lectures," published in 1895, and although it is thirty-six years since I wrote the first article, I think I may be pardoned for giving herewith a few extracts from it, as it shows that the views I then held, and still hold strongly, have by the latest mode of treatment been confirmed, i.e. that the derangement called milk fever in cows has its origin in the udder, and the real exciting cause is the *removal of the pressure by the too sudden withdrawal of all the milk either before or after calving*. Will you, Mr. Editor, kindly excuse me if I record a real canny old Cumberland "crack" which took place in 1872, and prior to writing my first article, and which was the means of drawing my attention to the udder as being the seat of the exciting cause. It was in the parlour of a well-known and eminent agriculturist and stock-breeder, the late Mr. John Blackstock, of Hayton Castle,

Cumberland, a great friend of the Druid. Mr. Blackstock was a noted breeder of hunting and carriage horses, and highly bred Shorthorn cows, and he suffered heavily from milk fever amongst his fine bred animals. On this particular night he said to me "Doctor,"—a title he always gave me—"I have just been at the Duke of Devonshire's, Holker Hall, buying a young pedigree bull, and I have had a long chat with John Drewry," at that time the well-known herdsman of Holker Hall, "he has just come back from London, where he has been making enquiries of the London dairymen," who at that time bred calves, "if they had got any preventive for milk fever, and the reply was, not to milk the cows for two or three days after calving; leave them alone, and then only take small quantities at a time several times a day. Drewry has tried it and found it to answer." "Now, Doctor, what do you think of that; does it stand to reason to leave a cow with a big udder so long without milking?"

After some meditation I concluded that the idea was right and in accordance with nature's laws, and the following reasons bear it out, which I have extracted from the article I wrote in 1877:

"1st. Would the calf if left with the parent, as it would be in nature, take all the milk at once from the udder? Decidedly not.

2nd. The mare is seldom, or never, troubled with this malady.

3rd. It is rarely, if ever, seen in ewes, simply because their offspring are allowed to take small portions of milk as often as they like, drawing it from the udder in very little quantities."

But this is not so with the cow, more particularly the deep milker, which is most liable to the affection, and often about the third, fourth, or fifth calf, because the gland by this time, from excessive usage, becomes more developed, not only to supply milk for its young, but also dairy produce for mankind.

As the time draws on for calving, the udder becomes enlarged and gorged, pressing upon the nerves of that organ to such an extent that sensation must be totally or partially deadened—paralysed. This state continues for a few days, but as soon as the cow calves, down sits the milkmaid and draws off all the milk at once, thus removing the pressure that has existed for some time. Reaction next sets in, which the writer is led to believe is somewhat analogous to the pricking, tingling sensation, which every one has at some time or other experienced, by "sleeping" as it is termed, of the leg or arm; this peculiar feeling being transmitted along the sympathetic nerves of the body, causing uneasiness and general nervous derangement, which is still further increased not only by the recent expulsion of the foetus, but also by the removal of the calf from the presence of the mother, thus causing a collapse of the secreting portion of the udder, and total cessation of milk.

It stands to reason that the elements entering into the composition of the "colostrum," or "beastings," which are of a nitrogenous nature, and at this time contained in the system of the cow—

more particularly if the animal is a deep milker—would naturally be eliminated from the body by the function of the udder. But as the udder is not acting, these elements are retained in the circulatory system, where they not only act as a foreign body, but have a toxic effect on the nerve centres, and cause the peculiar excitement seen in the early stages of the derangement, this excitement being succeeded by total prostration of the whole nervous system, in which all the organs of the body participate, and is followed by congestion of the structures.

Therefore, as a preventive of this very frequent and fatal malady, I strongly recommend that the udders of all heavy milkers be drawn six to eight times during the twenty-four hours for the first three or four days after calving, or until the milk is said to be clear of the "beastings," taking from three pints to two quarts each time. For the last four or five years, or since our friend named the matter to us, a number of our employers and others have adopted the plan, and we are glad to say with highly successful results. We now and again meet with a case, and upon inquiry find that immediately the animal calved she was "clean milked and well stripped."

I may here state that the late Mr. Blackstock tried the experiment of not milking the cows, for two or three days after calving, on some Irish cattle with the best success before adopting it in the high bred animals, and although the udders were hard and distended no case of mammitis or other ill effects followed.

The foregoing remarks and extracts, go to show that the sudden removal of the pressure from the nerves and blood vessels of the udder, by the withdrawal of all the milk at once is no new idea, and I quite agree with Mr. Blackwell's last paragraph, that is, "do not milk the cow for forty-eight hours after calving, but allow the calf to suck in the natural way." The latter mode of leaving the calf with its dam, for the first three or four days after calving, has been regularly practised for more than thirty years by a number of breeders in my district.

With reference to Mr. Huband's note, that the idea of not milking the cows, or leaving the calves with the cows, has escaped the notice of our teachers and those who have contributed to our literature on the subject, I may say that I have lectured to the students of the Aspatia Agricultural College for nearly forty years, and have strongly advocated these measures, whilst they have also been recorded in all the four editions of my Elementary Veterinary Lectures, which Mr. Huband most likely has not seen.

The case I have now to record is as follows: I was called to a cow on Sunday at noon, July 6th, said to be bad with milk fever. The cow had been well doctored by the owner with an agent called in this locality "the lifter," a preparation of Chloral hydrate, and in the hands of almost every farmer about here. She was in a semi-conscious condition, and as the man thought she would come through with the "lifter" I left her alone, but towards night

she gradually grew worse, and became comatose. I therefore distended the udder with air injected into the teats by the means of a special fitting to a bicycle pump. In eight hours the cow was on her legs and seemed quite correct. Twelve hours later she had a collapse and went down again, and became quite unconscious. The udder was again injected, and within two hours—marvellous to say—she was up again and made a complete recovery, and was sold within a week. This is only one case of many of a similar character in which the simple distention of the udder with atmospheric air has been used. (The best plan, I have found, for the removal of the air is to put the calf to the cow, as the sucking by the calf brings the udder soonest to its normal condition). From the rapid recoveries by this simple means—returning the pressure as it were—I am strongly of opinion that there is no septic material about the derangement: the changes take place too quickly for septic action. There exist only disordered functions, due to the *sudden removal of the pressure* which, I think, is the whole crux of the question, and the distention of the udder again with air goes to prove that my views of nearly forty years ago are being verified.

My definition of milk fever in cows is, therefore, a mechanical disturbance inducing a physio-pathological derangement, which is again restored to a normal condition by simply mechanical means,

HENRY THOMPSON, M.R.C.V.S.

Aspatia.

"AN OPEN JOINT."

Ten weeks ago one of my clients called my attention to one of his van horses as it had a small punctured wound six inches below the elbow joint, about the size of a shot corn, and was discharging a very small quantity of bloody serum. The animal was perfectly sound, and had worked two long journeys—about 60 miles—since first it was noticed. I advocated the use of antiseptic lotion, rest, and green food, also to place the horse in a loose-box, thoroughly expecting that in the course of a few days nothing further would be required.

This expectation was not realised, as I was called to examine him again, and found a swollen joint, very lame, and a case for deep consideration. Hot antiseptic fomentation was prescribed, a dose of physic administered, and the animal was placed in slings, which were taken to splendidly. Several days elapsed with no further developments, then I noticed a collection of fluid round the point of the elbow. Exploration found pus, and this was evacuated to the amount of about a quart. A surgical wound was carefully made so that drainage could be obtained, and I, personally, undertook the future dressing. Under treatment this wound healed; still the horse remained very lame, and the limb useless. Several days later the original punctured wound commenced to discharge "joint oil," and in spite of various dressings, which have in other cases been used successfully, the discharge became

more copious, and several other points of discharge appeared. I then ordered a hose pipe to be laid on and cold water applications to be applied continuously.

During the whole period in slings the horse ate and drank both well and heartily, consequently not much condition was lost with the exception of the muscles of the affected limb and shoulder, but as no progress was being made, and the owner's patience having vanished, we decided to slaughter and finish it off. This was carried out, and twenty years experience got a shock—one of the recurring ones we get, if not too conceited to admit them—and a condition of things which is good for a superabundance of egotism, if the unfortunate possessor of such a temperament is not too far gone.

I had the skin carefully removed, and over the area—where the punctured wound showed itself—the whole of the underlying tissues were broken down and purulent. Following this area upwards we had quite a channel direct into the elbow joint, and from several other parts the contents of the joint—joint oil—was passing to points on the skin where it was evacuated. But the surprising feature has yet to be related, the joint itself was very greatly involved, the surface of the inner condyle of the humerus was eroded and completely fractured, the head of the ulna was fractured, and there was a splintered fracture of the radius. These, of course, were in a more or less partially united condition, but still they were obvious to a casual observer, and the presentation of such a condition as here related is, needless to say, a subject for serious reflection.

It is not so much the case as described to which I would draw attention, but the possibilities of not having been sufficiently careful in my earlier examination; but what appears strange to me—on recapitulation of the whole case is, how, and when did the fractures arise?

The driver states—and I have every reason to believe him, that to his knowledge no accident occurred to the animal; the first thing noticed was the small puncture, and the slight discharge, she worked several days afterwards, and was not lame. The lameness appeared gradually, together with the swelling. No evidence of fracture presented itself—perhaps, and it is probably correct, I did not sufficiently examine the joint, owing to a preconceived diagnosis. Yet, so far as I can judge, the fracture must have been in existence at the time and, further, is it not uncommon in these cases to find an animal so slightly affected constitutionally?

The moral in this case seems to point to one thing—submit your diagnosis to further consideration, as well as your patient.

W. BROWN.

Workshop.

The Director of the Pasteur Institute, M. Roux, reports experiments which have been made by MM. Nicole and Conseil with serum taken from parotid glands of patients who were suffering from mumps. A number of monkeys were inoculated with the serum, and a mild form of the disease was produced, which gave immunity against further infection.

CLOVE OIL FOR OPEN JOINT.

About six weeks ago I was asked to look at a lame horse. Examination revealed a small wound on the outside of the leg, about an inch below the fetlock joint. Instructions were given as to cleansing and dressing, but the wound was not probed. A few days afterwards a splinter of wood appeared at the orifice, and was removed. Following this the leg commenced to swell; pain and lameness became excessive, and synovia appeared. The wound was syringed three times a day with corrosive sublimate solution, an antiseptic pad put on and retained with a calico bandage, and on top a thick woollen bandage from the coronet to the knee, soaked in weak Jeyes' fluid solution and pulled tight. After about four days of this treatment the animal was worse than ever; the bandages each time were soaked with synovia. The leg was badly swollen—no weight placed on it, and emaciation was rapid, the horse lying most of the time. By now the wound cavity appeared to run round the back of the fetlock, and would hold a 10 c.c. syringe of liquid. Having read in *The Veterinary Record* some time ago that clove oil is recommended for open joint, I syringed out the wound, injected about 1 c.c. of this into it twice daily, keeping my finger on the exit for about one minute to allow of penetration, then applied the antiseptic pad and bandage. This caused rapid filling of the cavity by granulations, and closure in about four days, a big excrescence of proud flesh growing on the wound orifice completely closed it. After closure, the leg swelled worse than ever, but bandaging, and later a blister were employed for reduction purposes, and the animal is almost sound again.

I do not maintain that the wound was into the fetlock joint. It may have involved from its position, either it or the sesamoid bursa, or the sheath of the flexor tendon—or all three. The symptoms, however, were very urgent, and pointed to very serious lesions, and I am confident, after this experience, that open joint need not be despaired of, if a fair amount of immobility can be secured, and the wound kept aseptic. In this case microscopic examination of the discharge at intervals showed that sepsis was maintained throughout.

F. J. DUNNING, G.V.S.

Lydenberg, Transvaal.

ANOTHER PECULIAR CASE.

A case came under my notice similar to the one described by Mr. Maquire. It is now some eleven years ago when one morning I was called, or rather sent out to see a cow which, by the description of the messenger, had a great difficulty in breathing. I found the animal presenting these symptoms:—In great distress, standing with fore legs wide apart, eye staring, "fixed" in its socket, livid in colour, nostrils dilated, animal breathing very rapidly, with a difficult inspiration, pulse rapid, the whole energies of the animal seemed to be in the act of breath-

ing. I had never previously seen a case similar in the cow; but I drew my conclusions from similar symptoms in the horse, and decided I had to deal with a case of asthma. I gave a stimulant; left another to be given in three hours time, and I called again the same afternoon, when the original symptoms were much the same, and to my surprise there was a huge swelling extending from the withers and the fore legs along the sides and back as far as the anus and the vulva. The swelling was crepitous, and upon puncturing the skin the exudate was of a frothy serous nature; devoid of blood, with the peculiar odour of the discharge from black-quarter. I, now along with my principal, came to the decision that it was a case of subcutaneous emphysema following asthma. The case starting in asthma causing emphysema of the lung with rupture of the smaller air cells and the pleura, the air escaping and working its way along and between the loose tissue surrounding the blood vessels and eventually leaving the thorax by the brachial or dorsal exits. In this case it was evidently by the brachial, as the first appearance of the swelling was just behind the scapula. Our case ended fatally about the fourth day, and unfortunately no post-mortem was made.

UNO.

EASTERN COUNTIES
VETERINARY MEDICAL SOCIETY.

A meeting was held on Thursday, July 24th, at the Great White Horse Hotel, Ipswich. In the unavoidable absence of the President, Mr. F. B. O. Taylor, who was engaged in London, Mr. F. M. Wallis, Halstead, was voted to the chair. Others present were Messrs. T. G. Heatley, Woodbridge; T. J. Faithful, Hadleigh; P. Turner, Ixworth; W. J. Browning, Ipswich; T. E. Auger, Wymondham; A. F. Castle, Phillips, Ipswich; Sidney Smith, jun., Lowestoft.

Apologies for absence were received from Sir John M'Fadyean, Messrs. F. L. Gooch, W. Shipley, J. E. Kitchin, H. V. Low, J. Barr, H. F. Downe, B. W. Bloomfield, Sidney Smith, Sen., M. Bray, W. Turtill, H. E. Wilkinson, A. H. Santy, Jas. Robertson, H. Buckingham, J. Buckingham, J. Hammond, E. H. Leach, W. Waters, J. R. Godbolt, A. P. Burgon, D. S. Jack, J. Bee, J. F. Thurston, E. Margaron, E. A. Hudson, A. McTurk, C. C. Nesling, J. Cleveland.

CONDOLENCE.

The CHAIRMAN said before they took the business it was only right he should express the grief and sorrow they all felt at the loss by death of one of their members, Mr. W. M. Reeman, of Bury St. Edmunds. He was sure they would all wish to extend their sympathy to Mrs. Reeman in this great trouble, and he moved that a letter of condolence be forwarded by the Hon. Secretary.

This was carried in silence, the members upstanding. Mr. Reeman's death created a vacancy in the auditors, and on the proposal of the Hon. Sec. it was decided to fill this at the next meeting.

The minutes of the last meeting were taken as read and adopted on the proposal of Mr. Auger, seconded by Mr. Heatley.

Next Meeting.—Mr. HEATLEY proposed that the autumn meeting be held at Great Yarmouth. Mr. Auger seconded, and this was agreed to.

The HON. SEC. said he had received a promise from Mr. Sidney Villar to read a paper at the next meeting, and it was resolved, on the motion of the Chairman, to invite Mr. Villar to take for his subject Bovine Tuberculosis, with special reference to diagnosis.

CLINICAL CASES.

The HON. SEC. said he recently had a case of œsophagotomy. The patient was a little black and tan dog with a lump in its throat, and on examining it he could only conclude there must be something stuck in the œsophagus. Obviously the only thing to do was to attempt an operation. He gave two-thirds of a grain of morphia hypodermically, and anaesthesia was completely successful. He had no difficulty in performing the operation, and on cutting into the œsophagus took out a piece of hard cartilage about the size of half-a-crown. He took the usual precautions in regard to asepsis, and sutured the œsophagus with catgut and the skin wound with silk. The dog made an excellent recovery. It was not exceptional, but it was undoubtedly rare to get a case of obstruction of the œsophagus.

"Cæsarean" on a Bitch.—The pup was dead and attempts by traction simply brought away bits, while the main part of the fetus remained out of reach. The only thing left was to attempt the Cæsarean operation. He had the animal at his infirmary and used 1½ grains of morphia, and when anaesthesia was complete, was able to perform the operation. Both horns of the uterus contained fetuses. Finding it impossible to complete the extirpation of the uterus with the whole of contents, he made an opening in one of the horns whence he removed the fetuses, four living and four dead. He then removed the whole of the uterus, stitched up the muscle and skin and put the bitch in a kennel. She lived nine hours, and then died from collapse. She recovered consciousness completely, but the membranes were very cold, and she never looked like living.

The next problem was to save the pups. He placed them in front of the fire in a blanket with a hot water-bottle. One was weakly, and was promptly knocked on the head. To the other three lactol was given every two hours from a feeding bottle, and they were kept quite warm by changing the hot water bottle at intervals. After three days of this, he was able to secure a foster-mother, and the pups were with her and had every appearance of doing well. As they were exceedingly well bred it quite repaid the trouble taken. He mentioned the case as showing that the cæsarean operation was well worth trying. It would have been impossible to deliver these pups alive in any other way, and in any case the bitch would have died. As the result three pups were kept alive.

Mr. HEATLEY asked how long after morphia administration, complete anaesthesia was obtained?

The HON. SEC. replied in from a half to three-quarters of an hour.

The CHAIRMAN said these cases were very interesting and he had had several. Some had been successful and some had not. One was a bull bitch in the same condition as the Hon. Sec. had described. Several pups were dead, but there were three live ones. He performed the cæsarean operation and removed six or seven pups from the uterus. The three live ones he took care of, and they all lived about six months, but came to a bad end; two were killed accidentally. There was no doubt that part of the uterus was gangrenous from the dead pups. She was a valuable bitch, but lived only about ten days. A friend told him if he ever had such a case again to take away the whole uterus or else he would lose the bitch every time. He had always done so since, but even then it was not always successful. The case might have gone too far before they got a chance to operate. Morphia was a perfect godsend in

canine practice, and he would not be without it now but he did not find it so successful with cats.

Mr. HEATLEY enquired what the dose was for an ordinary fox terrier?

The CHAIRMAN said he gave up to 1½ grains.

The HON. SEC. said he thought one grain sufficient.

The CHAIRMAN said 2½ grains was the quantity for a retriever. They sometimes had cases of pus in the antrum in big sheep-dogs and morphia was wonderfully useful. They did not feel anything, and the great thing, especially with regard to the cæsarean operation, was that they laid quiet so long after it without interfering with the dressings.

Mr. HEATLEY said he had lately examined some animals for insurance, amongst them was a three-year-old Shire filly. She had not foaled up to time, and was a fortnight over when he was asked to see her as she was suffering from abdominal pain which he naturally thought was foaling about to commence. He found no efforts at foaling, no preparation, the os in perfectly normal condition. He treated her for an attack of indigestion, and she got all right. A fortnight later she had not foaled, and at that time her body was distinctly smaller and the mare was looking listless. He saw her again several times until she was nine weeks overdue; there was no alteration in the condition of the vagina or os. As the mare was insured, the owner was getting anxious, and the insurance company was inclined to disclaim liability. She eventually died, having lost condition very much, got very weak and hidebound, just dragging herself about. He asked the insurance company to send a representative to the post-mortem, as he felt sure it would be an interesting case. This was done, and they found the uterus contained a fully developed fetus. There was considerable peritonitis of an adhesive nature. He noticed a loop of bowel was apparently firmly adherent to one of the concave horns of the uterus. Then a foot anterior to the os was a complete twist of the body of the uterus. He could feel nothing through the vagina, no tension, and no suspicion of a twist. He had thought it might be rupture of the muscular coat of the uterus. The twist was so complete that the diameter was no more than two inches. The uterus was cut into and a dark coloured fluid came away. The hair was just coming off the foal. He had never heard of a similar case. Probably the twist occurred in early pregnancy.

The CHAIRMAN said he had a cart mare die a few days before. The double colon was found twisted twice over and very full. He had never seen quite such a bad twist with the double colon so full before: it was as much as a man could do to twist it over. It was marvellous how such things occurred.

CENTRAL VETERINARY ASSOCIATION (IRELAND).

A meeting was held at Turner's Hotel, Cork, on the evening of July 8th. Mr. B. P. J. Mahony occupied the chair.

An apology for non-attendance was received from Mr. W. C. Patrick.

New Members Messrs. A. J. O'LEARY, E. J. O'RIORDAN, T. M. RYAN, Limerick; and T. O'LEARY, Macroom, were elected members of the Association.

The minutes of the last meeting were read and confirmed.

The HON. SEC. announced that he had no correspondence to submit to the meeting.

THE ANÆSTHETICS BILL. THE TUBERCULOSIS ORDER.

Mr. WINTER: Does the Anæsthetics Bill apply to Ireland?

Mr. HOWARD said that it would apply to every place where it was put into force. There was no likelihood of the measure being carried immediately, but there was no doubt that it would be brought before Parliament until it was passed. Personally, he thought it would be a foolish attitude on the part of the veterinary profession to show any antagonism to the Bill. They claimed scientific methods, and they ought to take advantage of every scientific method for the alleviation of pain, and instead of doing anything to oppose the Bill, he thought that they should write to the approaching meeting of the National Veterinary Medical Association, with the view of seeing what amendments were necessary to make the Bill a feasible and workable Bill. He thought that that would be the proper course to adopt instead of opposing the measure.

The PRESIDENT: I quite agree with you in a certain sense, but why should the Government make it compulsory on us. Do they make medical men do it?

Mr. HOWARD: The medical men have not been waited on to do it.

Mr. HEALY: It does not affect us so much in Ireland as it does in England. Of course, in England there are any amount of quacks, and they want to cope with them. That is the question of affairs.

Mr. CLANCY said that it would be a good job if it did away with quackery also in Ireland.

Mr. HEALY then referred to where a member of the profession had lowered the fee in castration practice.

The PRESIDENT: That is a matter that should be put in writing and we will deal with it.

Mr. HEALY said that he would do so; and the meeting then decided to write to the gentleman about whom the complaint was made.

Mr. WINTER: We are supposed to be still discussing the Tuberculosis Bill. The Bill does not prevent any man using an anæsthetic. A quack can use water and say that it was an anæsthetic.

The PRESIDENT: I think there is nothing to prevent him using it. In reply to a question by Mr. Winter, he said the Bill does not apply to yearlings, but to two-year-olds and upwards.

Mr. HOWARD then proposed that the Hon. Sec. should write to the Secretary of the National Veterinary Association asking that an effort should be made to have the Anæsthetics Bill so amended as to make it an acceptable and workable measure.

Mr. CLANCY seconded the motion which was unanimously adopted.

Mr. HOWARD said that in connection with the Tuberculosis Order, he was sure that all the members had got a list of the fees which were adopted in Dublin by the Veterinary Medical Association. He noticed, however, that certain gentlemen had held a meeting at Mallow, and he thought that that meeting was called to try and create trouble with the Association.

The PRESIDENT: I don't think there was any member of our Association present at that meeting.

Mr. HEALY: It was a meeting of the Veterinary Inspectors of Munster, but these people have no grievance at all to ventilate. They were never members of our Association.

The PRESIDENT: If they were members of our Association I would say that it would be a good thing for each province to take action, but where there is one Association working for the betterment of the profession, I think it was very bad policy on the part of these gentlemen to hold a meeting on their own behalf.

Mr. HOWARD: We had a meeting of the Association in Dublin, and after careful consideration we arrived at that scale of fees. It is the highest we can expect where the County Councils adopt the Bill.

The PRESIDENT: Mr. Healy is attending this meeting to-morrow, and Mr. Healy should tell these gentlemen that this matter has been discussed by the recognised

Veterinary Associations in Ireland, and that they should not go outside these Associations in connection with the matter. Tell them that we have taken action and that it is unnecessary for them to do so.

Mr. HOWARD: Our Association is the Association that is looking after the interests of the profession, but of course you can understand now, some of these men were attracted to that meeting, as an Inspector's meeting.

The PRESIDENT: What will be our decision?

Mr. HOWARD: I have great pleasure in proposing "We have considered the Tuberculosis Order and approve of the scale adopted by the Medical Veterinary Association of Ireland."

Mr. HEALY seconded the motion, and said he would lay that matter before the meeting to be held on the next day.

PRESIDENTIAL ADDRESS.

By B. P. J. MAHONY, M.R.C.V.S.

The PRESIDENT: I am sorry that our meeting to-night is so small in numbers. I thought we should have in attendance some young members who would benefit by the discussions that take place. However, I am glad to see such old and true-hearted members present, and I hope our proceedings will do much good.

Gentlemen, allow me to thank you for the honour you have conferred on me in electing me as your President for the coming year, and the more so as I am aware there are several other members of this Association far more worthy and capable than your humble servant to fill the Presidential Chair. But as you were so good as to bestow such a high honour on an humble member of your Association I shall do my little best to fill it, though it is with considerable diffidence I do so when I reflect on the many able members who were the occupants of this chair in the past. In doing so I will look to your co-operation and support during the time I have the honour to be your President, that you will overlook the many faults on my part, and I trust that my term of office will be pleasant and advantageous to us all. Were it not for the assistance I am sure to get from our worthy Secretary, and that I am aware of the good fellowship that exists amongst us as members of this Association, I would have shrunk from accepting so high an honour.

I am glad to see so many old faces at this, our first meeting for the coming year, and trust that when the curtain falls on 1913 you may still be busy members of the profession. It is an old saying that "you should practice what you preach," but I must admit I am not such a constant attendant at the meetings of this Association as I would wish to be, still I have a deep interest in every one of them, and in anything appertaining to the advancement of the profession, for I am of opinion that nothing tends to advance it more than these meetings, where we come together in a social manner, and in good comradeship, to interchange our opinions.

I am glad to see the young members amongst us, as it is to them we look to keep the standard of the profession flying and the good old ship afloat, and to steer it with an even keel amidst the rocks and shoals that beset it on every side.

When I look back to the time I had the honour of entering the profession, I am amazed at the rapid strides made and the good work done for the community, the alleviation of suffering to our dumb friends, and the prevention of the many dread diseases that were a scourge to the country. At the time I mention, chloroform and local anæsthesia, especially the latter, were scarcely ever used; now they are in every-day use, to the advantage both of the patient and the operator. Consider all the dreadful diseases that in my early days were so little known and practically no trouble taken to

prevent their spread through the country. Now, thanks to the advancement of science, they are comparatively simple and amenable to treatment, and to the Veterinary Branch of the Department of Agriculture and Technical Instruction also, these diseases are a thing of the past.

Speaking of what the profession has done, I may mention the last outbreak of foot-and-mouth disease. With the details you are all well acquainted. Were it not for the way in which the profession, to their credit, fought it, what state would we be in at present, with our ports closed and cattle trade at a stand-still?

And here I may mention the great loss we have sustained by the death of Mr. Hedley, who did not spare himself in advancing the profession, and who, although suffering badly at the time, fought it, and just as he was being crowned with the reward of having stamped it out, he was snatched from us, but it is a great pleasure to me to know, and I am sure you all will agree with me, that his place is filled by one in whom we all may place the greatest confidence, I mean Mr. Prentice.

In every outbreak, owing to the Department's diligence and care, they were able to confine it to their own area, whereas, I remember when the whole country was teeming with it, and the loss could be put down at millions. Now, thanks to the members of our profession, I hope that condition is a thing of the past.

The same may be said of pleuro-pneumonia, rinderpest, rabies etc. I know what was the work required in dealing with these diseases, for I had to deal with the last outbreak of pleuro-pneumonia in Ireland, now about twenty years ago, and I can quite fully understand the work in it, and although we stamped them out to the detriment of the profession, still we willingly did so for the betterment of our fellow men and the country. I am glad to see that the public are beginning to recognise the good we have done by the creation of new officers under the Dairies and Milk Shops Order, and the Tuberculosis Order. Though the salaries given in connection with the carrying out of these Orders are tardy and unremunerative, still it is leading towards a recognition of the good that the veterinary profession can effect. I hope that the young members will show that they are worthy of far greater regard than we are getting at present. It is in their own hands. It is for them to be up and doing, and taking advantage of the numerous means now at their disposal for the advancement of the profession. I must say that, personally, it would be a great thing for me to see our profession attain that high standard of efficiency it should hold amongst the other professions.

I hope our meetings during the year will not alone be instructive but enjoyable, and that we shall have some very interesting papers read. There should be a willingness among us to bring forward papers, and make our meetings worthy of attendance, and to know that when we come, some of us come at a little inconvenience, that we shall be able to say to ourselves that I was rewarded for the trouble I took in coming. I should like to have the elder members read notes on cases, and to bring as many specimens as possible, for I find these will be most interesting, especially to the younger members, who have not yet got the practical experience that will guide them on until they have attained that knowledge, when they, in their turn can do what we are now doing. And for the younger members to bring interesting papers, bringing to us new scientific light, so that they will wipe the dusty cobwebs from the brains of the old members, and by that means keep the Association flourishing, as it has been since it was started on such a good basis by the worthy members, some of whom I am sorry to state have gone to their reward, but who have left a foundation that I have no doubt is built on a firm rock.

I hope that we shall be able to arrange a place for our next meeting that will be suitable to most, if not all, of our members, for it is by the number of attendances that the soul of this Association is kept alive.

Last, but not least, I would ask every member to pay his subscription punctually. The amount is not much, but, like the bundle of sticks, when all the members' little mites are put together it will make a strong bundle that will resist any unlooked for adversary to break it, and that bundle, as our Hon. Treasurer had hinted to me, is very slender at present. I hope by the time I shall be relinquishing the chair to a more worthy member, that we shall be in a strong financial position.

I am thankful to you, gentlemen, for listening to me so patiently, and am sorry for taking up so much of your time, especially when I know that some of you are tired after a hard day's work.

Mr. HOWARD said it was worth their while to keep their Association going, and he was sure the President's able and interesting address would do much to encourage them in the useful work in which they were engaged. He therefore begged to propose that their best thanks be tendered to the President for his very able address. (Hear, hear.)

Mr. HEALY seconded the motion, which was unanimously adopted, and the President suitably replied.

Mr. WINTER: As regards the poor attendance of members at our meeting to-night, I wish to say that we cannot help it. It is not our fault, as we always do our best in the interests of the Association and the profession as well as our members. Whenever the members of our Association want us to do a job for them, they turn up in force, and now some of the profession want to do a job on their own account. I hope they will be successful, but I am afraid they won't, as they are not recognised.

The PRESIDENT: No matter how they turn up, we will continue our work. (Hear, hear.)

"A DAY IN THE LIFE OF A COUNTRY PRACTITIONER."

E. C. WINTER, F.R.C.V.S., Limerick.

Mr. Chairman and Gentlemen,—As Secretary to this Association I find the greatest difficulty in providing material for discussion at our meetings, and despite the assurances of our Treasurer, at the meeting held in Dublin in January, that he would see to it that we had a paper for our next meeting; that paper was not forthcoming, and the Limerick meeting in April was abandoned. It struck me on the 6th February last that a day's work I had done would not be unproductive of a discussion, and I took notes thereon, which I reproduce here for criticism.

1.—CHRONIC SPLINT LAMENESS IN A HUNTER, WHICH, FROM BEING A GOOD RIDER, BECAME A BAD HACK AND AN INVETERATE STUMBLER.

The splints, as is usual in these obscure cases, were small and not visible, but were multiple, and the heels became contracted, the frogs being well off the ground. The lameness had been intermittent all through the season, first in one leg, then in the other, and the owner, as is often the case, put the affection down as rheumatism.

Treatment.—Cutting down the heels till the frogs rested on the ground, and keeping ordinary white lotion bandages on the legs day and night while in the stable, and applying the cold hose as often as possible through the day. This treatment kept the screw going one day a week for the season, and a couple of mild biniodide of mercury blisters, and turning out to grass since has completed the cure.

I may add that splints in my country give a lot of trouble, owing to the large amount of lime in the soil, forage, and water.

In every case of long continued splint lameness you get contracted heels, and also, very often, broken knees.

2.—ORCHITIS IN THE DOG DUE TO LONG-STANDING GONORRHOEA.

The patient, a brown retriever, was so swollen about the testicles, scrotum, and the region of the prostate glands, that he was incapable of swimming and would have been drowned the day before, only that the owner had helped him out of the water.

Treatment.—Lead lotion freely applied several times daily to swollen parts; penis and sheath freely syringed twice daily with peroxide of hydrogen solution. After ten days the patient went home apparently all right, but for another week or so, as a precautionary measure, I repeated the treatment once daily. There has been no relapse.

3.—PICKED-UP NAIL : UNEXPECTED RESULT.

A brown van mare, six years old, picked up a packing-case nail about the docks. The driver removed the nail which he said drew little or no blood. Two days after, as the mare was very lame, she was brought in and put in slings. The wound in the off hind foot was opened freely, and a copious flow of synovia followed, and continued for a fortnight. The mare suffered intense pain, and none of the usual remedies seemed any use in stopping the flow of synovia. The patient was destroyed, and on post-mortem the navicular bone was found fractured.

Query.—How did the mare work practically sound for a day and a half?

4. The next item on the programme was a visit from two cats at a railway station, and another from a collie dog. One of the cats had chylous ascites very badly, and a dose of prussic acid put paid to her account. Post-mortem revealed tuberculosis of nearly all the internal organs. The other cat was a male, of roving disposition; emasculation cured this propensity.

The collie has a large chancre on his penis, which a pair of large scissors quickly accounted for, and a touch of liquor ferri perchlor. completed the treatment. The lady in question wanted to know if copulation next day would hurt the dog, as she had a bitch ready for him. I asked her in the interests of humanity to give him a chance until next time. My assistants in these cases were two parcel clerks and the ladies themselves, and the operation theatre the parcel office.

5. The next case presented no difficulty, and was a chronic enlarged fetlock which only required a few absorbent blisters, applied at intervals of a month or so, and has done well.

6. Next came a bad schirrous cord in a four-year-old farm horse. I had, of course, to employ an anaesthetic, and was prepared for the case. An enormous mass of tissue was removed by blunt dissection from the off side, and the cord ligatured after removal. The mass removed was the usual cylindrical one, about eight inches long and from four inches, tapering down to one, in diameter. A smaller growth was removed from the near side.

I instructed the owner to pull off the ligature, ends of which I left long and hanging from the wound, on the fourth day. He did not do this, as he was afraid to interfere, and brought me in the horse on my next visit to the town, a month after. There was still of course a considerable swelling about the parts, and I had to cast the horse to get the ligature away. In spite of all the neglect, the case was a successful one. The only thing the owner did, was to keep the wounds irrigated with a solution of Hyd. perchlor.

7.—ACTINOMYCOSIS : ABSCESS

A couple of cows next presented themselves; one with wooden tongue, in which case the usual Pot. iod. treatment was adopted—and successfully; and the other with a post-pharyngeal abscess, which I lanced internally and blistered externally. This cow was a bad "snorer," but is now all right.

8.—WARTS.

Next came the most repulsive job of the day, namely, cutting off several large and a multiple number of small sessile warts from an old cart horse. This operation—an annual one, was also done under an anaesthetic, and was of course left till last, owing to the dirty nature of the work. Several pounds of warts were removed from all sorts of situations, but strange to say none of them interfered with the harness, and the resulting wounds were dressed with Ferri perchlor. Owing to the fractiousness of the horse, no after treatment is ever adopted. This fractiousness is not surprising, and I begged the owner to have the poor brute destroyed, but he refused.

(9) Was merely an examination for soundness and possessed no features of interest.

(10) This was a case of opacity of the lens in a hunter colt, said to be due to a stroke from a branch when galloping after the hunt which crossed the field he was grazing in. There had been a good deal of inflammation and running from the eye for a month before I saw it, but on this date it was to all intents and purposes a blind eye, and has remained so since.

I trust, Mr. Chairman and gentlemen, that my "mixed bag" will give rise to a discussion from which we can all learn something. I do not profess to have shown you anything wonderful, nor do we want anything wonderful to discuss at our meetings. We all see cases every day that someone else would perhaps treat differently, and possibly better than we do, and it is only by an interchange of opinions we can learn something from one another.

DISCUSSION.

The PRESIDENT: This has been a very interesting paper, and I am sorry that there is such a small meeting, because the matters Mr. Winter has referred to, would give rise to a very good discussion.

Mr. HOWARD said they ought to be very grateful to Mr. Winter for preparing such an interesting and instructive paper for their meeting. He had referred to a good many little odds and ends that had made his paper most enjoyable, and the members were grateful to him. He (Mr. Howard) in course of his work came across a good many cases of splint lameness, and especially with young horses, that were considerably knocked about while suffering from splint lameness. He had such cases also with hunters, and he would like to say that he believed no one could improve on the treatment that Mr. Winter had adopted in the cases he had told them about. Speaking of such cases in general, it was his experience that the best treatment was not to use the animal while lame. If they did they would find him more lame three weeks afterwards. His own treatment was to lock the animal up and have the concussion removed until he was sound. That was the most effectual treatment that they could have.

The case of Orchitis was dealt with very effectively by Mr. Winter, and he (Mr. Howard) need not pass any remarks with regard to it.

With reference to the horse that picked up the nail, he thought that it was very hard to decide at any time what really happened in these cases. It was absolutely impossible to decide whether the fracture of the navicular bone took place at the same time as the puncture by the nail or whether it came on subsequent to the

injury to the feet. He had a similar case some time ago. The nail was pulled out of the foot and he afterwards went a journey of six miles, and was not affected by it to any noticeable extent. However, on the very next day the animal was very lame. He got treatment, and it turned out satisfactory, in this way—that the horse was working at the present time, but with a very fine ringbone. He believed that the horse fractured the pedal bone several days after the original injury from the nail, and he believed that that was due to the awful soreness that there was in the foot.

The case of the schirrous cord to which Mr. Winter had referred was undoubtedly very favourable, and he would like to know if Mr. Winter's plan was to have a ligature in removing such a growth. It ought to be the proper course, considering the large amount of hæmorrhage in such cases. He (Mr. Howard) saw a horse some time ago, eight years old, but it had been castrated as a yearling, and it had a terrible schirrous cord. It had gone all that time with it. They could not understand it, but the animal was now doing very well.

As to the case of the colt's eye he would like to know how soon after the injury to the eye did Mr. Winter see it, and what was the extent of the injury on the first day; because it was not usual that such a slight injury from the touch of a branch would lead to the loss of the use of the eye. He would also like to know from Mr. Winter and the other members, their opinions, as regards the number of cases of cataract that would have their origin from similar injuries to the eye, and whether such cases had any injury at the start. Personally, he thought the cases of cataract were not the result of injury.

Mr. HEALY said that he would like to ask Mr. Winter what strength of Peroxide of hydrogen, he used in the case of the dog to which he had referred. He (Mr. Healy) did not agree with the last speaker in his remarks on rest for splint lameness. He thought a great deal of lameness was due to small undetected splints in the bone, and it was his practice to give the animal as much work as was possible on soft ground, and treat them with the old treatment, and then to get them at work and send them on the road. He remembered a case of a horse that had won a prize. That day the horse went lame, but he used the old fashioned treatment on him, and that animal had gone sound ever since. There was an old M.F.H., Mr. Fitzgerald, Clanmilt, and his idea was to work such animals on soft ground, and he always got good results.

As regards the case of schirrous cord to which Mr. Winter had referred in his very able paper, he would like to know whether it was extra scrotal, or inter scrotal, when he put on the ligature.

It was his experience of eye wounds that, when the wound was deep it punctured the eye-ball, and that these were serious cases, and would always give trouble, but when the wound was only superficial, there would be no trouble with the treatment of the eye. In conclusion, he wished to say that if they had more papers of the type of Mr. Winter's, they would have better discussions than was the case with long theoretical papers that wanted time to consider.

The PRESIDENT said that he desired to join with the other speakers in thanking Mr. Winter for his interesting paper. He had had a very wide and long experience with splints, and he should say that he agreed with Mr. Howard about rest and also blistering in such cases. When the animals did not give in after two or three blisterings, he used a fine needle, and then blistered again, and he found that that left no mark. He could tell them that such treatment was very effectual. He was very much for rest. What brought on the splints? He thought it was the concussion, and if they kept up the action by setting the animal at work, they were

bound to keep up the irritation. He thought that rest was necessary in the treatment except with heavy draught horses, which should be put to slow work. He found with race-horses, which were very troublesome, that they got sore shins, and that in such cases rest and blistering was the best treatment. When inflammation was in evidence, the white lotion was very good, and in a good many cases that, with rest, would be sufficient. One of his cases was a hunter, and until he applied the needle the animal did not get right. A race-horse which he had under treatment he gave rest for six months, and it regained its action, which it had previously lost.

He would like to know if Mr. Winter ever used iodoform in such cases as that of the dog he had mentioned?

Mr. WINTER: I have only used peroxide.

In the case of the picked up nail, the President thought that the bursa must have been punctured, while, as regards the schirrous cord, he found a good many of these cases in old horses all internal. He had taken them off externally in two-years and three-year-olds. He never had much difficulty in the treatment.

In the eye case that Mr. Winter had mentioned, he would like to know how long it was from time it occurred until Mr. Winter saw it.

Mr. WINTER: Over a month.

The PRESIDENT said that in the case of an external injury to the eye, he used calomel. He was of opinion that where the internal chambers of the eye were destroyed, that they never again were restored.

THE L.G.B. (SCOTLAND) APPOINTMENT.

Mr. HOWARD said that he desired to draw the attention of the Association to the action of the Local Government Board in Scotland, in appointing as veterinary inspector, a man who was not a veterinary surgeon at all. He believed that the Association should take up such a matter.

Mr. WINTER: The various teaching schools have lecturers and examiners who are not veterinary surgeons, and they could get plenty of them. I think we ought to protest against men being appointed teachers and examiners, who are not veterinary surgeons. We have plenty of men in the profession capable of doing such work.

Mr. HOWARD proposed that the Secretary of the National Veterinary Association be asked to bring the matter up for discussion at next meeting of his body, because the Central Veterinary Association (Ireland), were of opinion, that the time had come when the teaching staffs at the various Veterinary Colleges should be recruited from the veterinary profession.

Mr. HEALY: In Continental schools they have no one but veterinary surgeons.

The motion of Mr. Howard was agreed to.

The PRESIDENT said that though their meeting was a small one, they had done an amount of work. (Hear, hear).

The proceedings then concluded with a vote of thanks to the President.

YORKSHIRE AND NORTH MIDLAND VETERINARY ASSOCIATIONS.

A meeting took place in the Town Hall, Sheffield, on Friday, July 18.

The LORD MAYOR (Ald. S. Osborn) in extending an official welcome to the members of the two Associations and their ladies commented on the fact that the Yorkshire Association was apparently celebrating its jubilee by a matrimonial alliance with the North Midland Association, which, he said, was an admirable if somewhat

belated event. The statement that the founder of the Yorkshire Association was the person to whom the song of the "Village Blacksmith" was dedicated, suggested that the profession of veterinary surgeon was evolved from the farrier of past days. If this was so, they had a very healthy origin—an origin which suggested high ideals and honest work well done. Medical science was perhaps one of the greatest features of the day, and it was an interesting fact that medical science as applied to human beings and animals seemed to be coming into contact. So far as tropical diseases were concerned it seemed rather difficult to decide whether the veterinary surgeon was becoming a medical practitioner or the medical practitioner a veterinary surgeon, but it was very obvious that in the interests of national health there would have to be greater knowledge in both these branches of medical science, the health of the people being so much tied up with the health of animal life.

There were present: Messrs. Joseph Abson, President, Yorkshire V.M.S., and Mrs. Abson; Frank L. Somerset, President, North Midland V.A., and Mrs. Somerset; Dr. O. Charnock Bradley, J. Clarkson, J. S. Lloyd, Mrs. Lloyd, and Miss Katie Lloyd; Philip Deighton, W. Crawford and Mrs. Crawford; S. Wharam, Frank Halliday, Geo. Whitehead, J. Hodgman, C. S. Smith and Mrs. Smith; G. E. Bowman and Miss Bowman; Arthur Ellison and Mrs. Ellison; M. Robinson, A. McCarmick, Herbert Nixon and Mrs. Nixon; Bruce Selous, J. S. Woodrow and Mrs. Woodrow; H. P. Lewis, R. Hudson and Mrs. Hudson; H. R. Laycock, C. S. Hunting, P. Abson and Mrs. Abson; A. D. Morgan and Mrs. Morgan; J. H. Yates and Mrs. Yates; T. C. Fletcher and Miss Fletcher; S. E. Sampson and Mrs. Sampson; Miss May Lodge, J. H. Gillespie and Mrs. Gillespie; Miss Alice Lever, S. H. Nixon and Mrs. Nixon; E. G. Johnson and Mrs. Johnson; H. Thompson and Mrs. Thompson; F. W. Pawlett, W. Collinson, T. Ludlow, G. Green and Mrs. Green; and G. Howe and Mrs. Howe.

"THE PRESENT DAY VETERINARY SURGEON AND HIS SUCCESSOR."

Dr. O. CHARNOCK BRADLEY, M.D., D.Sc., M.R.C.V.S.,
Edinburgh.

In his address Dr. Bradley said that to understand adequately what was the position of the profession in 1913, it was necessary to ask: What had been the past of the profession? That the veterinary surgeon originated from the farrier, that was to say from the blacksmith, was in essence, absolutely true, but the farrier was not the only predecessor of the modern veterinary surgeon, for in 1844, when the first Charter was granted, and when the profession became one of the learned professions, it was a matter of very considerable debate in veterinary circles as to whether the alleged veterinary surgeon prior to 1844 was quite the sort of person out of which a profession would evolve. It was, in fact, stated that the veterinary surgeon previous to 1844, and, indeed, for some little time after that date, was very little more than a groom, a hanger-on in stables, and often a more or less undesirable person from the point of view of a learned profession.

He mentioned this because if they contrasted the position of the profession sixty years ago with the position to-day, they could not be otherwise than perfectly satisfied with the progress that had been made. It was a matter of congratulation that in so phenomenally short a time the profession should have become what it had.

Respecting the nature of that progress, it had been said that sixty years ago the profession had more practical men than it had to-day—that the young practi-

tioner of to-day was far too scientific and not sufficiently practical. His reply was that in his opinion scientific knowledge without practical application was useless. The really practical man, and the man who counted, was the man who was capable of dealing with emergencies, and was not tied to familiar phenomena. Further, it was very often the case that the old practical man was famed for his lightning diagnosis, but he thought that one of the facts upon which the veterinary surgeon of to-day could pride himself was that lightning diagnosis had become less common—that more thorough examination was made before the diagnosis was arrived at—and that he had shaken off some of the shackles of the popular tradition that he must know everything, and that he must know it all at once.

The profession was at last coming into its kingdom. Veterinary science was at last becoming recognised as it ought to be. It was taking its own place in line with medical science.

The future veterinary surgeon would attain the kingdom through many channels. It was realised now that a veterinary surgeon could not be "produced" in a short time at a veterinary college. All that could be done in the way of education was to prepare him to teach himself, and he (Dr. Bradley) ventured to hope that the future veterinary student would do more with his fingers than in the past.

There was no question whatever that the young veterinary surgeon had to prepare himself for preventive as well as curative medicine. The duty of the surgeon of the future would be rather to prevent diseases, and not so much, perhaps, to cure them. This prevention would come about, he believed, partly through eugenics—by paying attention to the ancestry of animals and preventing the production of young from unsound parents. Through eugenics, veterinary science would be of greater and greater importance to agriculture in its widest sense. There was a distinct feeling among agriculturists to-day that good stock paid—that pedigree stock, all other things being equal, was better than ordinary mongrel stock.

Another direction in which progress could be made was in the greater utilisation of instruments of precision. There was no reason why such instruments as the ophthalmoscope and the laryngoscope should not be used practically every day. The plea of their being no time to use them might be advanced, but it would be recalled that the same plea was advanced about the use of the microscope.

A further direction along which progress would be made was indicated in the words "extension of Empire." Empire, or civilisation, would never advance without some assistance from some source of veterinary science. Civilisation was impossible without animals, and animals were impossible unless they could be kept in health in unusual and almost abnormal conditions. In this connection he instanced the development of South Africa. The prospects of the future were, therefore, of the best, despite the assumption of the man in the street that the profession was no longer necessary because of motor traction.

"In spite of all the statements that the layman has made, I think we may rest quite assured that the motor car has not done a material, or a lasting, damage to the profession as a whole, and that the prospects are as good to-day as every they were—indeed, one might almost say better, for the reason that the outlet for activity is greater to-day than ever it was, and for the reason, furthermore, that there is distinct evidence that advance in veterinary science will be greater in the future than in the past; and it will not only be greater, but it will be more rapid." (Applause).

Dr. Bradley was heartily thanked for his address, on the proposition of Mr. J. Clarkson, M.R.C.V.S., of Leeds,

secretary of the Yorkshire Association, seconded by Mr. J. S. Lloyd, F.R.C.V.S., of Sheffield, secretary of the North Midland Association.

Following Dr. O. Charnock Bradley's address, short business meetings were held.

At that of the North Midland Association, Mr. Somerset, the President, was in the chair.

Apologies for inability to be present were received from Messrs. J. S. Wheatcroft, W. Brown, W. Bowett, E. Marrison, W. Murgatroyd, and W. W. Norwood.

A letter was read from Mr. F. W. Garnett, Treasurer of the International Veterinary Congress to be held in London next year, soliciting subscriptions towards the Congress Fund, and stated that several hundred pounds were still required.

Mr. T. LUDLOW, M.R.C.V.S., was unanimously elected a member of the Association.

Mr. CLATER WILKINSON was nominated by the Secretary on behalf of Mr. W. Brown, seconded by Mr. T. C. Fletcher.

The SECRETARY read the report of the Council meeting held on the 2nd ult., recommending that accounts to the amount of £6 15s. be paid, and said that a letter had been received from Mr. A. Noel Pillers, F.R.C.V.S., asking the new Association to affiliate to the Northern Branch of the National Veterinary Medical Association.

Pending some further enquiries to be made to the Secretary from Mr. Pillers, it was recommended that the matter be deferred for further consideration at the next quarterly meeting in October.

On the motion of Mr. Fletcher, seconded by Mr. Johnson, the report of Council was adopted.

After lunch at the Grand Hotel, where the members of the party were the guests of Mr. J. Abson, Sheffield, President of the Yorkshire Veterinary Medical Society and Mr. F. L. Somerset, F.R.C.V.S., of Chesterfield, President of the North Midland Association, forty-nine of the party were taken by motor charabanc to Buxton, tea being partaken at the Empire Hotel, a photograph of the party being also taken. Visitors leaving Sheffield by train were sent forward in an advanced motor charabanc so as to enable them to catch the train leaving Sheffield shortly after 8 p.m. The remainder of the party arrived at Sheffield at 9 p.m. punctually, after thoroughly enjoying the scenery of the Derbyshire Peak.

Through the kindness of Messrs. Hunter, photographers, Buxton, I also enclose proof of photograph for reproduction.

J. S. LLOYD, Secretary.

THE NATIONAL ASSOCIATION OF VETERINARY INSPECTORS.

The first annual General Meeting of the Association was held in the Caledonian Room of the Holborn Restaurant on Monday, July 28th, Mr. J. Abson (President) in the chair.

Present: Messrs. D. G. Davies, Swansea; D. Pugh, Sevenoaks; Wm. Hill, Dunstable; W. Stanley Carless, Worcester; H. Hide, Edmonton; F. Morton Wallis, Halstead; J. Bishop Young, Braintree; W. R. Williams, Bridgend; A. S. Adams, Dursley, Glos.; R. Bryden, London; W. S. Mulvey, Chelmsford; C. Blackhurst, Broughton, Preston; F. T. Prince, Ashbourne; T. Eaton Jones, Liverpool; John S. S. Woodrow, Swinefleet; H. H. Truman, March; Percy S. Howard, Wanstead; W. D. Halfhead, Ongar; R. Jones, Towyn; J. Hughes, Llanfair; C. Secker Smith, Barnsley; Edwin Armstrong, Newport, Mon.; E. H. Pratt, Northallerton; E. W. Morris, Uckfield, Sussex; W. Caudwell, Chertsey; James D. Rankin, Colne; Geo. P. Male, Reading;

Richard Hughes, Oswestry, Salop; Fredk. Leeds Gooch, Stamford, Lincs.; Alfred Over, Rugby; Geo. A. Banham, Cambridge; John Cameron, Berwick-on-Tweed; Geo. Wartnaby, Burton-on-Trent; Hugh Begg, Hamilton, Lanark; W. R. Emery, Guildford; Robert Barron, Blandford, Dorset; Fredk. T. Trewin, Watford; Henry G. Lepper, Aylesbury; Geo. Elmes, St. Albans; Geo. F. Vincent, Sutton, Surrey; John F. Healy (visitor); P. J. Mullane (visitor); R. MacGregor, Market Harborough; J. G. Parr, Leicester; C. Pitts, Bradford; J. Pollard, Halifax; Percy J. Simpson, Maidenhead; Sidney Villar, Amersham; C. F. Hulford, Haslemere; J. H. Carter, Burnley; C. E. King, Abingdon; W. W. Grasby, Daventry; E. Lyne Dixon, Margate; James Crowhurst, Canterbury; John Dunstan, Liskeard; Theodore C. Toope, Dover; J. W. Brittlebank, Manchester; Trevor Spencer, Kettering; G. H. Locke, Manchester; J. C. Coleman, Swindon; William Hackett, Donington, Spalding; F. T. Harvey, St. Columb.

Apologies for absence were announced from Messrs. T. J. Simpson, L. W. Heelis, R. S. Pethick, Prof. Gofton, Geo. Jelbart, R. L. Phillips, J. MacKerlie, G. Edmundson, A. H. Gentle, J. J. Crowhurst, Geo. Gibbings, John Brown, J. R. Dykes, Chas. Morgan, J. McKinna, T. Slipper, W. J. Young, W. E. S. Richmond, A. W. Noel Pillers, Kenneth Rankin, W. C. Watts, Peter Wilson, A. R. Routledge, W. G. Senior, W. C. Barling, D. Forwell, John Malcolm, Arthur Holl, J. Marshall, H. O. Richard, A. Green, R. L. Green, J. P. Railton, W. Blunsom, T. E. Auger, J. K. Calderhead, G. L. Harber, W. G. Wagstaffe, J. Clarkson, Geo. Howe, T. Ludlow, Fred Watchorn, J. W. Pritchard, T. Chambers, A. B. Forsyth, H. J. Dawes, W. J. Powell, W. Roach, James East, Fletcher, and others.

The HON. SEC. (Mr. Trevor F. Spencer) read the notice convening the meeting; and on the motion of Mr. Banham, seconded by Mr. Toope, the minutes of the last special general meeting were taken as read and confirmed.

The following gentlemen were nominated as new members:—Messrs. P. Gregory, Tonbridge; E. R. Harding, Salisbury; T. Chambers, Dudley; W. J. Powell, Newport Pagnell; T. J. Simpson, Ruthin; J. H. Truman, March; R. Jones, Towyn; James Rankin, Colne; J. S. S. Woodrow, Swinefleet; H. K. Roberts, Bexley Heath; E. Franklin, Worcester; H. B. Hiles, Worcester; A. G. Elder, Tewkesbury; R. K. Rutherford, Bromsgrove; J. M. White, Tenbury; J. A. McLauchlan, Astley, Stourport.

On the motion of Mr. T. F. Spencer, seconded by Mr. Toope, these gentlemen were elected members of the Association.

The PRESIDENT said he desired to draw the members attention to the rules. The Council had gone very carefully into the matter of drawing up suitable rules. They had been guided in a large measure by the National rules. If it was the members' wish that the rules should be read *seriatim*, the Council was quite willing to fall in with that suggestion, but taking into account the fact that the Council had had the rules under their consideration for a long time, he thought he might ask them to take his word for it that the rules were applicable to the Society.

Mr. LEPPER said he thought the members ought to know the rules by which they were bound, and he proposed that the rules should be sent round to all members.

The PRESIDENT said he would call upon the Hon. Secretary to read the rules *seriatim*.

The HON. SEC. read the first six rules.

The PRESIDENT said with regard to rule 6, the Council had had applications from registered practitioners, and he desired to put it to the members whether they thought it desirable to admit registered practitioners to the Association. The Council had discussed the matter,

and had come to the conclusion that it would not be policy, and against the rules as they stood, to admit existing practitioners as members of the Association. He would like to hear the views of the members on the point.

Mr. HUGHES asked if it had been ascertained whether many other existing practitioners were acting as inspectors under the Contagious Diseases of Animals Act.

The PRESIDENT replied there was quite a number. He was going to take the sense of the meeting on the point, because it was rather a crucial one.

Mr. HUGHES enquired whether the matter was restricted to those who were already acting as inspectors.

The PRESIDENT replied it did not matter whether they had already acted or whether they were going to act.

The matter as to the inclusion of existing practitioners into the Association was then put to the meeting, and resulted in favour of such gentlemen not being included.

The SECRETARY then concluded reading the rules.

The PRESIDENT pointed out that the rules would be binding until twelve months hence, when at the next annual meeting it would be incumbent upon anyone who desired to see any alteration made to send a notice into the Secretary 21 days before the annual meeting, and then any rules that were not to the liking of the members could be amended. Mr. Spencer reminded him that the rules could be altered before they were passed on the present occasion, and if any gentleman had any observations to make he would be quite willing to hear him.

Mr. J. CAMERON said he took exception to the rule which said that no other business could be taken at an adjourned meeting except what was left over from the first meeting. It might be that three months would elapse between the two meetings, and something else might have occurred in the meantime. If there was sufficient notice given, why could not that fresh matter be taken at the adjourned meeting?

The PRESIDENT pointed out that there was nothing whatever to prevent the members holding another meeting. It was only a question of notice, and it could be held at the same time as the adjourned meeting.

Mr. MALE moved that rule 11 should be altered to read: "Any member whose subscription is two years in arrear shall be struck off the list of members after having been notified by the Secretary."

Mr. W. S. MULVEY seconded the motion.

Mr. TRUMAN proposed as an amendment that the rule should stand as formulated.

Mr. CROWHURST seconded the amendment, which was put and carried.

The amendment was then put as the substantive motion, and carried.

On the motion of Mr. Lepper, seconded by Mr. Secker Smith, it was agreed that the rules should stand as read.

PRESIDENTIAL ADDRESS.

J. ABSON, F.R.C.V.S., Sheffield.

Gentlemen,—When in a weak moment I accepted the position of your President during the formation of this Association and subsequently when it was formed, I overlooked entirely that a Presidential address at this time would be required of me. I frankly admit here and now that at speaking and writing I have been a miserable failure all my life, and I frequently wonder what on earth I am doing in my present position—why I should occupy it at all to the exclusion of others so admirably fitted to hold it. I, therefore, having admitted my shortcomings claim your indulgence and your support during my year of office.

The Tuberculosis Order has now been with us three months, the ice has been broken, the ship liberated and allowed to get under way. I think the breaking of the ice has been, perhaps, the most difficult. At the outset of the Order we were threatened to be engulfed, so numerous were the cases reported, but that contingency would appear to have disappeared so far as my experience goes. During the short existence of the Order the major portion of the piners have doubtless already disappeared, whilst the fact that many animals affected with tuberculosis, and which would have probably been showing marked evidence of the disease have got a new lease of life for the time being, consequent upon their living an out-door life.

So far as I can ascertain, and speaking generally, I believe the Order has worked comparatively smoothly. A knowledge of one's cases, combined with tact and judgment, is responsible for this. There have been, and necessarily will be, cases off the beaten track occurring from time to time in which we may find considerable difficulty in arriving at a proper solution.

I have frequently been told that the tuberculin test is being much abused by some. If this is true it is greatly to be regretted. It is not according to the circular letter from the Board dealing with the Order, nor to our practical promise to Sir Stewart Stockman. You will notice I used the word "Abuse," none of us will deny that it is sometimes necessary, but my own experience tells me that to carry out the provisions of the present Order it is *rarely necessary* to use the test; I am, however, open to correction.

Perhaps one of the most difficult problems besetting the Inspector is where a local authority having the milk clauses, such as many of the large towns possess, finds tuberculosis bacilli in a mixed sample of milk from a farm or dairy of another local authority. Formerly the veterinary inspector of the first-named authority had to discover the culprit giving the affected milk, and doubtless those towns which have whole time officers will continue as before. But there are many authorities who, up to now, have not had a veterinary officer for this purpose, and many of such will avail themselves of the opportunities presented by the Tuberculosis Order to have the sources of their external supplies inspected without cost to themselves. Thus the Sanitary Authorities having ascertained that the milk from a certain farm had been found to cause tuberculosis would notify the authority in whose district the infecting farm is situated. They, the latter, would notify their local veterinary inspector, and it would be his duty to find out the actual cow or cows responsible for the infection. Now, often, this is by no means an easy task and may result in several visits having to be paid, and a great deal of time spent on the case before a satisfactory solution is arrived at. First, the whole of the cows must be carefully and thoroughly gone over. Any with the least suspicion of udder trouble must be marked down and different samples of milk taken and examined microscopically. A control sample of the unsuspected animals will help you in this. A process of gradually weeding out will have to go on until you get the right animal or animals. In such cases as these the biological test may frequently become necessary where the udder lesions are not marked, and the microscopic test unsatisfactory.

There appears to have been considerable trouble with the dual valuations in some districts. It did appear at the outset a somewhat anomalous instruction. But on carefully thinking the matter over, the Order on the point is quite sound and feasible. The Order is not a philanthropic Order, it is an Order destined to do away with clinically affected animals that are wasting from tuberculosis, and animals giving tuberculous milk—both of which forms of the disease are a danger to the community as well as to the owner himself. It is

without doubt an advantage to the owner to rid himself of an animal that is capable of disseminating the disease among others of his stock. I think to this end he should lend his whole-hearted support to the working of the Order. Does he, speaking generally, do so? I fear not. He rather views the Order as irksome, and as interfering with the liberty of the subject, losing sight of the chief reasons which caused the framing of the Order. Personally, I think it only right to be fairly liberal in the case where an animal to be slaughtered bids fair to be passed for food. But in the case of an emaciated tuberculous carcass, in which the hide only is of any value, the minimum of 30s. is just and equitable. It is clear that the Order does not desire the owner to lose either directly or indirectly, and consequently when a cow is properly valued, he is covered even in the event of mistaken diagnosis by the veterinary inspector.

Many Inspectors appear to have some difficulty with the microscopic examination of milk. Well, the tuberculous bacilli are not always easily found, and where they are few and elusive I confess one's patience may be sorely tried and the fee be more than earned—indeed where a succession of slides have to be prepared and examined it is quite possible several hours may be taken up. I hope, however, by this time that practice has made everyone proficient, and that none of the members find it necessary to send more milk samples than they can help to bacteriologists for microscopic examination.

And now a few words about fees. It has been admitted by many local authorities that the fees proposed by this Association are fair and reasonable for the duties required. As to the justness of the fees we stand as one man. There are some inspectors being paid a fee in excess of those prescribed by the Association. Against that we have no complaint, in fact we congratulate them. But we have a *bona fide* grievance against quite a number of local authorities who are underpaying their Inspectors, who have fought tooth and nail for the reduction of the fees—and I regret to say, in some cases, have succeeded—belittling the profession and their duties under the Order and diverting some of those duties into other channels, thereby setting the Order at defiance. In several cases threats have been used to employ all-time men.

In one district the handsome fee of 5s. for the first hour and 2s. 6d. for every hour afterwards was being paid. In these cases, I think, this Association should act, providing it is the wish of the inspectors concerned and provided always they belong to this Association.

DISEASES OF ANIMALS ACT, 1894 TO 1911

Return showing the number of Premises on which the existence of TUBERCULOSIS has been notified to the Board of Agriculture and Fisheries during the month of July, 1913.

† Counties affected, animals attacked: London 3, Warwick 1, York, West Riding 2.

Board of Agriculture and Fisheries, Aug. 5, 1913.

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

The Ductless Glands

It has long been known in medical science that the human and lower animal organism have within them a considerable number of bodies known as glands, and that these glands manufacture and store up some special fluid according to their kind, and we have, in many cases, thought we had found out all there was to be known about them. However, within the past year or two a considerable amount of information has been forthcoming in reference to the physiological effects of the secretions of certain of the glands, such as the thyroid in the neck and the adrenal glands on the kidneys. The example which I am about to relate shows conclusively that the presence of the ovaries exerts a mysterious physiological influence, for, when removed, the most astounding pathological effects were manifested.

In April three years ago at a caponizing demonstration at Graaff-Reinet, at which there were over forty farmers and townsmen present, Veterinary Surgeon Elley removed the ovaries from three hen ostriches. The hens were each four years of age at the time. Shortly after the operation the three hens began to assume the black body plumage of the adult cock bird, and, from the characteristic drab colour of the feathers of a female, these feathers turned jet black and glossy as in the male. The wing and tail feathers also changed, and became so like those of the cock bird that feather experts to whom they were shown declared them to be the typical feathers of a cock ostrich.

These hen ostriches belong to Mr. W. Rubidge, a well-known Graaff-Reinet farmer, and he kindly consented to have one of them chloroformed and presented to the Port Elizabeth Museum for exhibition. The bird was sent to us in the flesh, and I had the satisfaction of making a personal examination to make quite sure it was a female.—(Mr. F. W. FITZSIMONS, Director of the Port Elizabeth Museum, in *Agricultural Journal of the Union of South Africa*).

Prosecution by the R.C.V.S.

Herbert Alfred Glover, a young man, of Mayes Place, Croydon Road, Warlingham, was summoned at the instance of the Royal College of Veterinary Surgeons, for unlawfully using the description of "Member of the Royal College of Veterinary Surgeons," on June 2nd. Mr. G. R. Thatcher (Essex Street, Strand, London) appeared for the prosecution, and Mr. Percy Holt (Purley) for the defendant, who pleaded guilty.

Mr. Thatcher said the case was a very serious one indeed, and he would ask the Bench to impose at least the full penalty, which was £20. The defendant gave evidence in that Court on June 2nd. He took the oath, and in reply to the Clerk, said he was a veterinary surgeon, and was a member of the Royal College. He then gave evidence, as an expert, in a case as to the condition of a horse, as to which there had been a prosecution for cruelty. He was cross-examined by Inspector Fleming, of the R.S.P.C.A., and again said he was a qualified veterinary surgeon. He (Mr. Thatcher) could scarcely imagine a more serious case. It was most important that in all courts of justice the evidence of expert witnesses should be given by experts, and not by men who said they were. Otherwise the ends of justice would very likely be defeated. Defendant should consider himself most lucky that he was not in the box on a charge of perjury.

Inspector Percy Fleming, of Kenley, gave evidence as to two Whyteleafe men being charged with cruelty to a

horse on June 2nd, when the defendant gave evidence for the defence, and swore that he was a veterinary surgeon and a member of the Royal College. He attended the horse professionally, and gave evidence as an expert, and in cross-examination by witness again said he was a qualified veterinary surgeon. Witness saw the defendant about a week later, when he again said he was a veterinary surgeon, and that his name would be registered at Dick's College, Glasgow. Witness produced the Register of the Royal College, in which the defendant's name was not included.

Mr. Holt, addressing the Court for the defendant, said he had been very ill, and he came to the Court on June 2nd against the doctor's orders, and was very anxious to get away. He understood that the Inspector's question was put to him just as he was leaving the witness-box, when he felt very unwell, and he answered in the affirmative. He (Mr. Holt) could not help thinking that defendant did not think what he was doing, as he, of all persons, must have known that it was quite simple for anyone to find out whether he was a member of the Royal College or not. He had been a student of the College for four years, and passed the preliminary examination.

Mr. Thatcher pointed out that that did not make him a member.

Mr. Holt pleaded for leniency, remarking that he did not think the defendant had any intention of deceiving the Court, but did it without thinking, not feeling well at the time, and being anxious to get away.

The Bench retired, and on returning, Mr. Lloyd (who had taken the chair, Mr. Daniell having left before this case was heard) said they looked upon this as a very serious case. There was no excuse at all for the defendant's conduct. He would be fined £10, and £3 3s. the College costs, and 9s. 6d. the Court costs.

On the application of Mr. Holt, a week was allowed for payment, the total fine and costs being £13 12s. 6d.—*The Surrey Mirror*.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Aug. 1.

SPECIAL RESERVE OF OFFICERS.

ARMY VETERINARY CORPS.

Lieut. R. C. Wheeler is seconded for service under the Colonial Office. Dated July 17.

R. F. Stirling, F.R.C.V.S., late Lieut., A.V.C., to be Lieut., with seniority as from Oct. 2, 1911. Dated Aug. 2.

August 5.

REGULAR FORCES. ARMY VETERINARY CORPS.

Capt. J. W. Rainey retires, receiving a gratuity. Dated Aug. 6.

Personal.

Mr. WM. MARSHALL, M.R.C.V.S., Aberdeen, judged the Roadster Class at the Northern Counties Joint Show at Inverness on Friday, 25th ult.

Mr. A. B. TULLY, M.R.C.V.S., Kelso, was one of the judges of the Hunters at the 81st Annual Exhibition of the Cumberland Agricultural, at Carlisle, on Saturday, 36th ult.

Mr. A. SETON MILNE, M.R.C.V.S., has just been engaged by the Municipality of the City of Georgetown, British Guiana, South America, at a salary of £400 per annum.

OBITUARY

WILLIAM ANDERSON, M.R.C.V.S., Langholm.
Graduated, Edin: April, 1863.

Mr. Anderson died at Moffat on Aug. 4th, from senile decay. Aged 72 years.

ANDREW JOHNSTONE MCINTOSH, M.R.C.V.S., Dumfries.
Edin: April, 1862.

Death took place on Aug. 5th, from cerebral hæmorrhage, at the age of 73 years.

THE LATE SIR RICHARD POWELL COOPER.

A correspondent writes to *The Times* :—

"It seems to have escaped notice generally that the late Sir Richard Powell Cooper was by profession a veterinary surgeon. He studied at the Royal Veterinary College, Camden Town, took the diploma of M.R.C.V.S. (Lond.) in 1868, and subsequently was in practice at Lichfield. He was the nephew of Mr. William Cooper, M.R.C.V.S., who found a remedy for scab which, under the name of Cooper's Dip, has ever since been extensively used in all sheep-rearing countries, especially in South Africa, Australasia, and the Argentine. The business eventually came to Sir Richard Powell Cooper and another nephew, and is now known as William Cooper and Nephews. Sir Richard's experience as a veterinary surgeon was undoubtedly of great service to him as a stock-breeder. He continued to take an interest in the profession, and a year or two ago was in a deputation, with Sir John McFadyen and other gentlemen, to Mr. Runciman with a view to obtaining a more liberal State grant for veterinary education and research. He had also promised a substantial sum towards the expenses of the International Veterinary Congress, which is to be held in London in September of next year."

CORRESPONDENCE.

VETERINARY SURGEONS—AND THE FUTURE.

Sir,

Reading *The Veterinary Record* on Saturday last I noticed that, at the annual dinner of the National Veterinary Medical Association, Mr. Carter, President of the R.C.V.S., said :—"In spite of the advent of motor traction there were in Great Britain 1,500,000 horses, etc., etc., in 1911, and that 'those figures showed that there was plenty of work for veterinary surgeons, and he thought there never was a brighter prospect for the profession than there was at the present time.'"

Dr. Bradley made somewhat similar remarks at the combined Yorkshire and North Midland meeting in Sheffield. First let us investigate Mr. Carter's remarks about the number of horses, and here state that he is quite wrong in his estimate; he is wrong to the tune of 127,393, and his error is quite in his favour, because he can add this number to the one he quoted, then in spite of this increase to his quoted figures there is a decrease of 4.2 per cent., also the foal crops decreased by 13.5 per cent., or a loss of 19,000 foals, as compared with the maximum year 1905.

Further, his figures only concern horses on the farms of Great Britain, horses in towns or not kept on agricultural holdings, are not included. Now, will he tell us how the demand for horses has been affected in towns, where motor traction has been substituted, then we shall be able better to understand the meaning of his figures, or, better still,

get the opinion of members of the profession whose living is earned in town areas, then I think his "tidings of joy and great expectations" will receive a rude shock. There is no doubt that thousands of horses have, or in the immediate future, will be displaced by motors, and I have it on the authority of one whose business it is to work things out to a farthing, that for heavy and long journeys there is no comparison, the cost being in favour of motors, and these will, no doubt, become cheaper to purchase, easier to run, and less costly as a means of transport as time advances and brings them to greater perfection.

Dr. Bradley, no doubt basking in the "roseate hues," reflected from the knowledge of his secured position, tells the same tale. He advances the view that more municipal work will come into the hands of the veterinary surgeon of the future. But I would ask, Will preventive medicine increase the annual income of the general practitioner? Supposing for the moment that one veterinary surgeon is employed entirely, that is to devote his whole time to his duties in every town of, say, forty thousand inhabitants, will it increase or tend to decrease the combined earnings of the whole. Certainly it won't, and for this reason, that those specially engaged will act not in curing disease, but to prevent it, consequently there will be less to treat for the general practitioner. I may here say that I am not looking at the matter from a personal point of view, but let us have facts not "terminological inexactitudes."

Then there are other considerations—quacks, unqualified assistants, etc., etc., and with regret and resentful feelings we may add that these have evolved in many cases from grooms who have acted in that capacity for veterinary surgeons who have relegated to them work that they themselves should have undertaken—especially dispensing, and it is no unknown thing to become aware, through an advertisement, that So-and-so, late with So-and-so, M.R.C.V.S., is selling medicine as per his late employer's recipes.

Then there is the veterinary surgeon who will work practically for nothing to keep another man out, and in not a few cases of this sort the individual who resorts to these tactics is a successful member of the profession. Will this enhance the value of one's services? or will it make those services more in demand or appreciated when given under these conditions?

Finally, we have to remember that as the demand for town horses declines in this country, so it will naturally follow in others. Therefore, if in face of these obvious indications these gentlemen can see the bright future they so confidently prognosticated, the only conclusion I can arrive at, personally, is, that I envy them their optimistic frame of mind when based upon such debatable promises.—Yours truly,
W. BROWN.
Workshop.

MULE WITH FOAL.

Sir,

The article by Mr. Harvey on a mare mule with foal in your last issue reminds me that in 1885, at the close of the Bechuanaland Expedition, I travelled from Kimberley by mule wagon to Hopetown, which was then as far as the railway from Capetown had reached. Some time after we arrived at Hopetown, as I was passing through the station yard I saw a mare mule lying on the ground beside the placental covering enclosing a foal, evidently recently born. I believe that this mule, which would be 13½ hands high, was the same animal that got exhausted half-way on the road, when the driver burnt some rags under her nose so that she would inhale the smoke, and revive sufficiently to continue the journey.—Yours faithfully,

ALEX. H. GENTLE.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1310.

AUGUST 10, 1913

VOL. XXVI.

PROF. HARVEY CUSHING ON THE VETERINARY PROFESSION.

On the whole, the International Medical Congress just held in London has done credit to a great profession. But it is regrettable that one of its most prominent speakers should have chosen to cast an undeserved slur upon another profession, of the work of which he knew nothing. We refer to Prof. Harvey Cushing, whose references to veterinary development were typical of the attitude which those medical men who know least about us and our work often assume towards us.

Our correspondence column contains a letter from Mr. Wallis Hoare, which well shows how the learned Professor unconsciously revealed his own ignorance of a science whose practitioners he presumed to criticise; and we reprint also a vigorous protest from Sir John M'Fadyean, which appeared in *The Times*. Further comment seems unnecessary. Prof. Harvey Cushing's acquaintance with all things veterinary is evidently so limited that we cannot hope that Mr. Hoare's letter in these pages will be favoured by his perusal. But Sir John M'Fadyean's communication to *The Times* can scarcely escape his attention; and we trust that it may enlighten him.

SIR R. P. COOPER.

It is curious that, of all the obituary notices of the late Sir Richard Cooper that we have seen, not one pointed out that he was a Member of the R.C.V.S., and had once practised the profession. Had not *The Times* been good enough to insert a note from a correspondent drawing attention to this, the fact might have remained unrecorded in the public Press. Yet there can be no doubt that the late baronet's veterinary training and early professional experience contributed not a little to his subsequent success as a stockbreeder. Natural gifts of a high order he must have had—gifts of observation, of organisation, and of business acumen—but these might not have been of much avail if the hobbies which he invariably rendered profitable had been taken up with an amateur's knowledge only. His initial professional training, and the practical experience of animals and of farm life and affairs gained in veterinary work, furnished him with a solid groundwork of knowledge with which to commence his many agricultural enterprises. This is too self-evident to require emphasis, and it is very strange that a series of fairly full obituaries of so well-known a man should contain no references to his membership of a profession which certainly did much to equip him for his main life-work, and in which he retained an interest to the end. Apparently the old tendency to push the veterinary profession, and all that pertains to it, into the background has not yet died away.

UNSUSPECTED TUBERCULOSIS.

During a casual conversation with a few professional friends, "Tuberculosis"—and the rapidity with which this disease sometimes runs its course—came up for discussion. It was due to the fact that on a previous occasion I had stated that in some cases, a really fine and healthy looking animal could, and did die in a fortnight from this disease, and I was asked for corroborative evidence; consequently I looked up two cases which had conclusively proved this to me.

The cases both occurred on one farm, they were sisters; deep milkers; kept under ideal conditions, and were very fine specimens of the shorthorn breed—in excellent condition. In the first case, I was called to see the older of the two animals; she had calved two days previously but did not seem well—thus the request for my attention. I examined the uterus, naturally, but found things normal, her temperature was 106, off her feed, and a cough, noticeable owing to its frequency.

In spite of treatment, she daily grew worse, rapidly became emaciated, and died absolutely skin and bone on the 13th of the month—nine days after I first saw her, and eleven from calving.

A post-mortem was made, with the result that one of the worst cases of generalized tuberculosis presented itself. The uterus was alright, and there is no doubt that tuberculosis was the actual cause of death.

The following year, on August 30th, the own sister to the previous mentioned beast calved. She appeared unwell, and the owner, being anxious about her owing to her relationship, requested me to look at her. She presented symptoms similar to the other case, followed the same course, and died on the 13th of the month, and the post-mortem, as in the first case, was purely one of generalised tuberculosis.

Here, then, we have two apparently healthy animals affected with tuberculosis, and the act of parturition—a normal one—acting as an exciting cause, whereby within fourteen days both die from a disease which had never been suspected, although in existence.

My reasons for reporting these cases are, first, that it may enlighten those who, as yet, have not observed them; secondly, that it may not surprise them when they do; and lastly, as an incentive to those who are doubtful, when they have newly calved cows "wrong" after a normal calving and cleansing, to look carefully for signs of tuberculosis.

HORSE SICKNESS.

I enclose herewith a snapshot taken during my recent visit to an outlying district, to carry out horse sickness inoculation work.

The photo represents two varieties of the disease, viz., the Dik-kop, and the Cardiac with slight Dik-kop. The former is depicted with the pendulous head, and the swelling is of a more severe form, as evidenced by the attitude, although the cardiac is the more deadly of the two.

East Griqualand.

A CASE OF CHRONIC NASAL DISCHARGE.

By Major E. E. MARTIN, F.R.C.V.S., D.V.H., A.V.C.

Chronic nasal discharge cases are frequently some of the most troublesome a practitioner has to deal with and, as in a case that came recently under my notice, the source of the trouble proved to be one that is not commonly mentioned in text books. I thought it might prove interesting to record it.

The patient was an artillery horse of the light vanner type. He was at a small out-station which was visited monthly by a veterinary officer. I think I can best describe the case by giving a few extracts from the official record of the case.

7th January, 1913. This is apparently an ordinary case of catarrh with bi-lateral nasal discharge, slight rise of temperature and typical symptoms, except for the fact that there was a strong odour from the discharges. I was informed that this animal had had this smell from the nostrils, but without any discharge, for a very considerable time, in fact nearly all the time he had been with the Battery—he had been seen by veterinary officers at various times, but no conclusion as to cause was apparently arrived at.

4th February. Discharge ceased, but breath even more offensive.

15th February. Still no discharge, but breath can be smelt some yards away—had him galloped, but no great distress shown. Horse looks rather falling away in condition.

As the case was evidently doing no good and required careful watching and probably surgical treatment, I had him sent to the Station Veterinary Hospital, Bulford.

The symptoms noted on animal were:

21st February. Slight discharge from both nostrils, especially after exercise. An offensive smell at all times. No submaxillary gland enlargement. Careful examination of teeth does not dis-

close any disease. Feeds well, and not in bad condition. Tested with mallein with negative results. Facial sinuses explored with a gimlet with negative results.

The disease was diagnosed as probably, disease of the turbinated bones. All the facial sinuses were opened in turn and in no case was any disease found. They were flushed out daily for a long period in the hope that if there was disease deeply situated it might be reached.

I saw the case from time to time and could not quite make up my mind as to diagnosis. I could not reconcile the idea of their being any necrotic disease in the head, with the fact that the submaxillary glands showed no enlargement, and though I thought of and suggested gangrene of the lungs, I could not believe that a horse could keep fair condition, do good exercise, and show no temperature variation with gangrene or abscess of the lungs.

At times the discharge would cease for some weeks, but the smell was invariably there, though sometimes less than at others. Sometimes there was a deal of coughing.

The horse was kept until the 15th of July and was then destroyed.

The abdominal organs were quite healthy, the lungs and heart were removed from the chest by cutting through the windpipe and large vessels, and on looking into the windpipe I saw a collection of purulent material. The anterior lobe of the right lung appeared slightly larger than normal, and was found to be very fluctuating; squeezing it caused an increase of the pus in the right bronchus, with some bubbling of air; I found, in fact, that the anterior lobe was little else than an abscess cavity. On cutting into it a yellow creamy stinking pus escaped, together with a certain quantity of gas; the cavity was irregularly shaped, but it would hold about eight or ten ounces. It opened into one of the small bronchioles and so communicated direct with the bronchus and trachea.

All Army horses are provided with veterinary history sheets which form a record of their ailments from the time of joining the Service, and one would carefully look at this record to see if anything is likely to throw light on the present case.

The following are the chief items of interest. He was born in 1906, purchased in July, 1910, and posted to the Battery in December of that year. In the following October he had an attack of strangles, but was only in hospital nine days, and the Veterinary Officer's remarks on his illness were "Patient in good condition throughout. The abscess under jaw was opened and gave no more trouble."

The next entry was from the 5th May, 1912, to 30th June, 1912, for debility in camp on Salisbury Plain, and this entry for illness of nearly two months looks rather suspicious. Was there anything more than debility, and would not a subacute attack of pneumonia have been likely to set up the symptoms that were put down to debility?

There appears little doubt that we must date this abscess in the lungs either from the attack of strangles from which he suffered in October, 1911, or the two months' illness shown as "debility" on Salisbury Plain in May and June, 1912.

ABSTRACT FROM FOREIGN JOURNALS

EFFECT OF WASP STINGS UPON HORSES.

Ohler, of Neustadt, records this case. Boys were attempting to destroy a wasp's nest by the roadside with a long pole. The wasps were irritated, and fell in troops upon two horses passing along the road. The carman ran away; while the horses, which were harnessed to a heavily laden waggon, were stung by the wasps.

When the horses were got back into the stable, they threw themselves down and rolled. This apparently increased the pain, so that they underwent a veritable attack of frenzy. They became quiet after the subcutaneous injection of morphia, washing with Sal. ammoniac and water, and the application of menthol and glycerine in spirit.

In the evening, about seven or eight hours after the accident, the horses were trembling over the whole of their bodies. The temperature had risen to 104° F., the respiration was forced, and the heart's action tumultuous. The pulse rate was 30 per minute. Collapse of the heart appeared imminent, but was warded off by copious doses of Cognac and the subcutaneous administration of Ol. camph. fort.

The next day some amelioration was apparent, as the horses were calm and the cardiac action had improved. Fever still persisted, and the animals refused all food.

On the fourth day a moist eczema appeared on the neck and head, giving those parts the appearance of having been sharply blistered. The appearance of this eczema was coincident with a visible improvement in the condition of the horses. The

fever subsided, the appetite returned, and in a few days the animals could again be used for work. The eczema was treated with a 1 in 3000 sublimate solution, and healed after five days.—(*Münchener Tier. Woch.*)

INTRADERMIC INOCULATIONS OF TUBERCLE BACILLI AS A TEST FOR THEIR VIRULENCE.

E. Burnet and C. Mantoux communicate (*Soc. de Biologie*) experiments which they have made with the object of determining whether the cutaneous tuberculous affections of animals, present characters analogous to human forms of cutaneous tuberculosis. They have made comparative inoculations of tubercle bacilli varying in virulence within and under the skin of the thigh in guinea-pigs, and also in the sole of a hind foot. From their experiments it results that intradermic inoculation of tubercle bacilli in the skin of the guinea-pig's thigh causes lesions more precocious and more extensive than does subcutaneous inoculation. The reverse is observed when the inoculation is made in the skin of the sole.

The precocity of appearance, the extension, and the depth of the lesions obtained by intradermic inoculation are dependent upon the virulence of the bacilli. This method therefore forms a rapid criterion to determine the virulence of bacillary strains—(*La Semaine Vét.*)

W. R. C.

NATIONAL ASSOCIATION OF VETERINARY INSPECTORS.

EXPERIENCES GAINED IN THE WORKING OF THE TUBERCULOSIS ORDER, 1913.* by HUGH BEGG, F.R.C.V.S., County District Veterinary Inspector, Lanarkshire.

Mr. Chairman and Gentlemen,—When Mr. Spencer, our energetic Secretary, invited me by telegram to initiate a discussion here to-day on "Experiences gained in working the new Tuberculosis Order," he was doubtless influenced by the knowledge that my Council had from the beginning welcomed the Order, and had proceeded to carry it out enthusiastically. That he ventured to risk the success of this meeting by asking one who is a comparative novice in debate to start the discussion was an indiscretion for which you will later on have the opportunity of calling him in question.

Perhaps you will excuse my temerity in acceding to his request on the plea that with plenty of opportunity I have had some practical experience of the working of the Order, although possibly my method of portraying my experience and making practical deductions may be somewhat faulty. It is not my intention to expatiate on the clamant need that has long existed for a more or less direct national assault on bovine tuberculosis. As a profession, we have intimate knowledge of the blasting of many stockowners' careers by the ravages of this fell bovine scourge, and we are not ignorant of the danger to man that lurks in the flesh and milk of the tuberculous animals. And though you and I, who have the privilege of carrying out this Order entrusted to us with such confidence by the Board of Agriculture, may

* Opening of discussion at First Annual General Meeting in the Caledonian Room of the Holborn Restaurant, London, on July 28th.

to-day be found making suggestions for the easier working of it that may merit the consideration of others, I feel sure that I express your candid opinion when I say that no order has ever emanated from the Board of Agriculture that has called forth such admiration from the veterinary profession and stockowners of this country as the Order now under consideration. Let us be thankful every day for the efficiency of the Board of Agriculture as a Government department which is thorough and up-to-date in its methods, and most obliging and helpful to local authorities. I think also that the Board are to be congratulated on the courage which they have shown in making the Order and insisting upon its enforcement notwithstanding the strong opposition with which it was met from certain quarters. Our experience in Lanark is that stockowners have shown every willingness to co-operate with the Local Authority in their efforts to administer the Order efficiently, and as was to be expected, the members of the veterinary profession have been most helpful in detecting cases of disease.

It would be an easy matter to criticise the Order on the ground of its limitations in dealing radically with the scourge of bovine tuberculosis. To do so would simply be to reiterate such arguments as we are assured Mr. Runciman and his advisers made use of in their attempt to force the hand of the Treasury before the Order was issued. It is therefore our duty, in gratitude to the Board and in loyalty to the veterinarian who has emancipated us by so well safeguarding our interests in this great work, to faithfully carry out the requirements of the Order, strictly observing its limitations, so that they may be able at the end of the year to show that the operations designed by them on the basis of the grant promised by the Treasury were statesmanlike and were founded on a clear practical knowledge of the subject.

To the veterinary inspector who realises his responsibility, and I am sure we all do, there is no duty placed upon him under the Order that he is not capable of fulfilling. Doubtless each of us has found little difficulties cropping up in one department or another—this was only to be expected in any new work—but each difficulty surmounted means experience gained, and fits us the better for future work, and especially for the more advanced steps that will eventually be taken to deal with tuberculous animals generally. After working the Order for three months in Lanarkshire, notwithstanding our desire for certain alterations on it, we consider it to be eminently practicable in operation.

Probably the surest method of embracing in our debate all the points worthy of notice will be to consider *seriatim* each of the articles of the Order, and refer as we proceed to any point which we think should be modified or amplified.

As you are aware, Articles 2 and 3 deal with notification by owners or persons in charge, and veterinary surgeons respectively. In the former case, the act of reporting automatically places the animal under the provisions of Article 9 (Precautions to be adopted with respect to milk) or 10 (Detention and isolation of suspected animals) as the case may be. Owners often plead ignorance of these provisions.

In that case, the inspector may, though he is not required to, serve on the owner a written or printed form embodying the requirements of Articles 9 or 10 or both. In all cases notified otherwise than by the owner, we have thought it expedient to serve one or other or both of these forms, unless the animal was one which obviously did not come within the scope of the Order. It will also be observed that Articles 2 (1) and 3 (1) require the Local Authority to inform the Sanitary Authority of every case notified; and that Article 4 (5) requires a copy of the Veterinary Inspector's

report to be sent to the Sanitary Authority; while Article 5 (1) requires notice of intention to slaughter to be sent to the Board. The Order does not require the result of the post-mortem examination to be sent to the Board or to the Sanitary Authority. It seems that there is a superfluity of reporting to the Sanitary Authority since (firstly) many cases are notified on very flimsy evidence, and (secondly) there is always a possibility that the inspector's preliminary report may be wrong. I suppose the object of informing the Sanitary Authority that an animal has been reported as suspect is to give that authority, should they see fit, the opportunity of taking steps under the Public Health Acts, yet the Veterinary Inspector's preliminary report is negative in a large percentage of cases, and I fail to see what interest the Sanitary Authority can have in any cases but those which on post-mortem examination are shown to be tubercular. Besides, the necessity of sending the preliminary reports to the Sanitary Authorities has the additional objection that it puts the officials of these authorities to needless trouble in cases that turn out to require no attention on their part.

Nevertheless, as already stated, the Order does not require the post-mortem result to be sent either to the Board or to the Sanitary Authority, and I submit that the only notification of value to the Sanitary Authority would be a copy of the post-mortem certificate of positive cases. We believe that this limited notification would better accomplish the object of the Order "in requiring notice to be given to the Sanitary Authority," because the evidence of disease having existed in a given herd would not be hypothetical but conclusive.

Respecting the fees payable to reporting veterinary surgeons, the first two paragraphs of Article 3 make it quite clear that the fee is payable irrespective of the result of the veterinary inspector's examination. That, I believe, is the intention, though I submit that the words "and are found to be diseased" in paragraph 3, are a little confusing.

Coming to Article 4, we see that while in Articles 2 and 3 the owner and the veterinary surgeon are expected to report animals suspected of suffering from:

- (a) Tuberculosis of the udder, indurated udder, or other chronic disease of the udder; or
- (b) Tuberculosis with emaciation, the indictment is here extended to include
- (c) Animals giving tuberculous milk.

The question here arises whether a veterinary surgeon who reported a cow as giving tuberculous milk would be entitled to a reporting fee. On a strict reading he would not, but I reckon no local authority would refuse it.

In inspecting and examining animals reported under the Order, to determine whether they can be put down under any of the above heads, any difficulty that arises under (a) and (c) is very much confined to the use of the microscope in determining the presence of tubercle bacilli in the milk. In Lanarkshire, which is perhaps more favourably situated than most counties, there is a fully equipped laboratory and an experienced bacteriologist, whose services are always available. Of the milk samples examined under the Dairies, Cowsheds, and Milkshops Order and the Tuberculosis Order, only a very small percentage that were negative in the smear have proved positive in the guinea-pig, and when this has occurred the lesions resulting from intraperitoneal inoculation after twenty-one days are very much less than those set up when a milk sample which gives a positive smear is tested biologically, the contrast in the lesions being due to the difference in the bacillary count of the two samples. The biological testing of milk for the purposes of this Order is so slow as to be markedly impracticable. Indeed, I would hesitate to keep a cow restricted under

Article 9, whose milk gave no result on smear examination, and I have never yet done so. It is our duty, therefore, to make the very most of smear examination. It would be unfair to lock up a cow's milk for three or four weeks which has passed a smear examination without compensating the owner, because fully 90 of such cases give no result biologically, and the danger that lies in the milk of the few that are caught in the guinea-pig is so small as to be almost negligible. I think the restriction should be withdrawn meantime, and in any case where the biological test is positive, the cow can be retacked without hesitation. To obviate, lessen, or justify this delay, the inspector should, at his discretion, take further samples for smear examination. Our experience is that unmixed samples of milk properly taken into sterile bottles and examined within twelve hours, never contain acid-fast bacilli that are not tubercle bacilli, and the county bacteriologist's method of staining is the simple Ziehl-Neelsen without elaboration. Some time ago, out of 31 samples positive in the smear, 14 were inoculated into guinea-pigs, producing typical lesions of tuberculosis, while in the other 17 cases the cows' udders were recovered and examined microscopically with positive results. In the face of that evidence one is not justified in sacrificing laboratory animals when the smear shows acid-fast bacilli.

The best method of taking a milk sample to get the largest bacillary count is a very important matter. In many cases the amount of secretion available is so little that we just take all we can get, stripping and drawing it off to the last drop. But in a quarter containing, say, 12 ounces, it appears to be a moot point whether the first, second, or third fill of a four-ounce bottle is the best sample to take. Mr. Brittlebank has decided in favour of the after-milk or strippings, and recommends massaging of the udder, with the object apparently of dislodging bacilli. Theoretically, this method would at once draw 100 per cent. of discipules, but while I do not wish to deny Mr. Brittlebank's statements, or oppose his opinion too strongly, it is my duty to say that, as a result of accurately conducted experiments which are published elsewhere, we found that the middle sample of milk often contained a bacillary count three times greater than the after-milk or strippings taken by the aid of massage. If Mr. Brittlebank has results to prove his opinion, probably the discrepancy between his conclusions and mine is to be attributed to inherent national characteristics of Scottish tubercle bacilli, which may be more easily captured by stratagem than by compulsion, and I suggest that it would be difficult to prove that, snail-like, they do not cling more firmly to the tissues when disturbed.

I need not delay by describing the well-known typical features of tubercular mastitis. In the great majority of cases the appearance of the secretion from the tubercular quarter guides us very little, though the deposit after centrifugalising, even the most normal looking of samples, usually possesses suggestive characters, viz., a grey coloured and more plentiful deposit than is yielded by healthy milk. Still, the deposit differs materially in appearance, but is not nearly so plentiful as that got from a sample of milk containing streptococci. It is my experience that no matter how long or how short the period is that a cow has been dry, if one of her quarters is tuberculous, it always contains some secretion, and this in almost every case is a clear yellowish salmon-coloured fluid showing very little deposit after standing a few hours. When such a secretion is got from an irregularly indurated and hard, painless quarter, you may reckon it contains tubercle bacilli every time.

Turning now from the milk cases to the third indictment head "Tuberculosis with emaciation," if your experience coincides with mine it will have involved at

times no small amount of indecision. For the first few weeks I confess that I interpreted the phrase liberally rather than literally, believing that animals with an abnormal discharge containing tubercle bacilli should be taken, even though they were in fair condition. My reason for so acting was based on the Board's circular letter to local authorities of date 25th March, in paragraph 3 of which they advise local authorities to instruct their veterinary inspectors with the view to avoid errors in diagnosis that—

- (a) In the case of cows suspected of having tuberculosis of the udder or giving tuberculous milk, samples of milk should be centrifugalized and examined for tubercle bacilli with the microscope.
- (b) In the case of animals suspected on account of an abnormal discharge, the latter should be examined microscopically for tubercle bacilli.
- (c) In the case of animals suspected to be suffering from tuberculosis with emaciation, but which are not suspected to be suffering from tuberculosis of the udder or to be giving tuberculous milk, all possible use should be made of the use of tuberculin.

You will notice that recommendation (b) dealing with cases with abnormal discharge is not tacked on or subsidiary to (c) tuberculosis with emaciation. At first, I believe that some elasticity of interpretation by the veterinary inspector was intended by the Board. Now, however, my understanding of the Board's intention is that "Tuberculosis with emaciation" is, for the meantime at least, to be literally interpreted (in all likelihood the returns they are receiving have something to do with this) and tuberculous animals are not to be slaughtered under this head unless, and until, they are really emaciated in the full sense of the term. The argument against including animals not advanced in emaciation will be further considered when we deal with Article 8.

Opinion with regard to what constitutes "tuberculosis with emaciation" may vary within wide limits. We might define the phrase as meaning any material loss of condition in an animal clinically affected with tuberculosis; but that would be an error, for, if the animal is not quite thin and wasted, and practically in the later stage of wasting from tuberculosis, we are not entitled to deal with it under the Order. And if the animal is not emaciated in that extreme sense, it is not intended that we should slaughter it, even though it be a criminal disseminator of disease, coughing up sputum teeming with tubercle bacilli. The fact that Clause (3) of Article 4 empowers us to take samples of the faeces or urine of any bovine animal on the premises, or of any abnormal discharge from any bovine animal thereon is not to be taken as implying that when any such samples are positive they are to be considered equivalent to a positive milk sample as a reason for slaughtering the animal. If, however, the animal is a cow-in-milk with a normal udder, I make an attempt to catch her for giving tuberculous milk while restricted under Article 10 only, and if the smear is negative, it is put through the guinea-pig. If the biological experiment also be negative, it sometimes happens that with the lapse of three or four weeks, the loss of condition may be such as to warrant taking her under "tuberculosis with emaciation."

That we have no power to put down such an animal is indeed a severe and serious limitation of our scope of action, since the animal that pollutes her stall with tuberculous sputum, faeces, urine, or uterine discharge, etc., must be a potent factor in spreading the disease and providing a future crop of cases.

The Board's reason for allowing such an animal to live is admittedly not a scientific one, but they do not require us to point out this—they are quite aware of it. It is on the ground of finance alone that they have not included such cases in the Order, and if failure to

include them seems suicidal, let us remember that it was necessary for the Board to draw a line somewhere, and that they are in a much better position than you or I to judge how much might be done with the means at their disposal, and without endangering the whole project by undue heroism in their first assault. We must also remember and be thankful that whereas up till three months ago the little that was being done by us in the fight against bovine tuberculosis was in most cases as assistants to others under the Public Health Acts. Now we have a Board of Agriculture Order giving us absolute power as inspectors within the limits of its Articles, and we may rest assured that when some experience has been gained, the veterinary advisers of the Board will know exactly what advice to give, when with increased grants from the Treasury it will be possible to widen materially the scope of the Order.

Although the Order has only been in operation for a short time, much valuable information has been gained already, both as to its practical and financial effects. It may be looked on as experimental to some extent, but I think it will be found that, within a period much earlier than was at first thought possible, we will be asked to deal with those forms of the disease to which I have referred, or in other words, that the time for "heroic" measures will arrive very soon. This will be brought about (1) by the recognition of the fact that unless we can get at all cases capable of spreading disease our work will be partially ineffective, and (2) by the fact that will, I think, be proved by experience that the question of financial compensation is not such a serious one as was at first anticipated. The Board are fully alive to all that is going on, and they may be trusted to take further action when they think that the opportune time has arrived.

Further, I am sure it is intended with a view to keeping down administrative expenses (which might conceivably reduce the whole work to an *impasse*) that we should, so far as it is possible, determine cases by clinical examination with a single visit. I have found this possible in quite a number of cases, and have on the spot arrived at a mutual valuation, and as required by the Order, served a statement of it on the owner, as well as a notice of intention to slaughter, and had the animals removed to the slaughterhouse on the same day. To use tuberculin in the case of an animal not advanced in emaciation is perhaps undesirable, for if the animal reacts, the owner naturally expects the case to be dealt with. It is my practice now to limit its use to non-febrile animals advanced in emaciation from an ill-defined cause, and which present no characteristic symptoms of lung disease or enlargement of superficial lymphatic glands etc.—very many of these when non-reactors prove to be the victims of Johne's disease. If any abnormal discharge from animals so emaciated is available, and is found positive when examined microscopically, the expense and trouble of tuberculin testing is avoided—besides, as you know, tuberculin is not always reliable in advanced tuberculosis.

In my experience, with the exception of strongylosis, pulmonary affections which yield on auscultation sounds indistinguishable from those of phthisis are accompanied by fairly constant fever. If in doubt it is my practice to restrict the animal under Article 10, when the owner may elect to have it treated or destroyed at his own risk. I grant that some of these may be cases of acute miliary tuberculosis of the lungs, or a combination of pneumonia and reactivated tubercular lesions, but while they are feverish I do not deal further with them unless I can secure some expectorate which proves positive, and the animal is emaciated. If this is not available, the victim of acute lung disease is likely to show some improvement or die in a very few days, and I fail to see that compensation should be paid for an animal that is palpably dying of a febrile affection.

Further, we have constantly to remember that the higher valuation is payable if an animal, however valueless it may be, is killed under the Order, and the post-mortem reveals no lesions of tuberculosis. Apart from pulmonary complaints, there are numerous pitfalls for the unwary inspector, *e.g.* septic conditions of the uterus, udder, digestive organs, the pleura, peritoneum, articulations, and feet; abnormalities and diseases of the teeth, pharynx, gullet, etc., parasitic affections, neoplasms involving important internal organs, and numerous other chronic conditions which are often associated with extreme emaciation, and demand for a correct diagnosis, so that their merits may be properly assessed, such an exhaustive clinical examination as can only be made by an experienced cattle practitioner.

Hitherto I have experienced no difficulty in arriving at a reasonable mutual valuation of all animals condemned, no objection has ever been made to immediate slaughter, and I am not aware that any owner has refused to accept my post-mortem certificate and the compensation that fell to be paid, except in one case where the owner of a cow slaughtered on account of a tuberculous udder erroneously thought he was entitled to the higher valuation because the disease was certified as "not advanced" on post-mortem, and the carcase had been passed by the inspector of meat.

Notwithstanding what has been said by some inspectors against our acting as valuers of condemned animals, I cannot believe that the man who is so well up in cattle practice as to be fitted to act as a veterinary inspector is not the best man to value diseased animals. For the sake of keeping down expenses they should frankly accept the duty, and I venture to say that in 95 per cent. of cases they will have but little if any trouble, and it is always open to them to fall back on an independent valuer, or the Board in exceptional cases. In fixing the higher valuation we need not be stingy, since it and the extra sovereign are only payable when we have erred in diagnosis, and in that event the owner is entitled to be dealt with liberally. Nevertheless, suitable deductions according to the type of animals should be made from its hypothetical maximum value for, say, the stage of lactation, the loss of a quarter or any diseased condition of the udder, loss of flesh, etc., etc. In settling the lower or diseased value, difficulty only arises in the case of cows in fair condition condemned for tuberculosis of the udder or giving tuberculous milk, the flesh of which may wholly or in part be passed for food. Here I consider one should value as fleshers would, who deal in such animals, erring on the side of generosity, and remembering that at best, three-quarters of the value only is payable, while at the same time not forgetting that the market value of such animals is at all times based on the knowledge that they suffer considerable wastage in the hands of the inspector of meat. We need not at any time, unless we care, value the animal at less than £6, because the minimum sum payable is quarter of the lower valuation or £1 10s., whichever is the greater.

Reverting again to "tuberculosis with emaciation," I conclude that few animals included in this category could be valued at more than £6. Our interest in valuing the latter animals merges into our consideration of Article 8—"compensation." In determining whether tuberculosis is "advanced" or "not advanced," it is provided under Article 8 (4) "that the disease is to be considered as 'advanced' when the carcase is emaciated and tuberculous lesions are present." The word carcase here includes all the organs, so it follows:

(a) When a live animal is condemned for "tuberculosis with emaciation," the carcase (provided no mistake in the diagnosis of the disease has been made) must also be tabulated "tuberculosis with emaciation," and be paid for at the lowest rate of compensation. The

veterinary inspector having in his preliminary report returned the case under the heading "tuberculosis with emaciation" would have but to find the presence of lesions, however infinitesimal in some part of an organ to conclude the presence of "advanced tuberculosis," since to record it otherwise would be a flat contradiction of his preliminary report.

- (b) If that argument is conceded, and if we were to deal under this head with cattle in fair condition of body because they had clinical evidence of disease, or were discharging material containing tubercle bacilli, it would inevitably follow in many cases that the salvage from the carcass would exceed the amount of compensation payable, and though the surplus would be payable to the owner, there would be an apparent conflict of opinion between the veterinary inspector and the meat inspector—a most undesirable state of affairs. That, however, is what we must be prepared to face if we include animals not quite advanced in emaciation and whose carcasses are not foredoomed to confiscation by the meat inspector. By demanding a literal interpretation of this heading, the Board ensure that at most only a few shillings fall to be paid by them as their share of compensation.

Nevertheless, I feel sure that if the Board were to extend the Order so as to enable us to deal with animals suffering from pulmonary tuberculosis and voiding tuberculous sputum, irrespective of their bodily condition, the amount of compensation payable per head would not be a serious matter, because—

(1) If disease were found to be "advanced" in post-mortem, only quarter of the lower valuation would still be payable.

(2) If the disease were "not advanced" it is practically certain that the whole or part of the carcass would be passed for food, and the salvage got in very many cases would defray the extra compensation payable. It is a sorry business to contemplate in this hot weather the lot of a coughing cow segregated under Article 10 in an odd shed, denied the freedom of pasture or the company of her neighbours, and waiting on the day when she will be thin enough to meet her doom. Again, we must remember that cases of open tuberculosis under detention need supervision, which means expense to the local authority. From a professional point of view this lack of power to deal with all open cases is, to my mind, the one stigma that attaches to the Order, but, of course, it is easy to use destructive criticism.

In Lanarkshire we convey the animals in a float to the nearest abattoir at our own expense, and send the hides direct to a hide market. The latter average about £1 in value—the condemned flesh fetches about 1 6d. per cwt., so that in these cases the cost to the Board is a mere bagatelle compared to the expense incurred by the Local Authority. We have advised our meat inspectors that a high standard is to be adopted with the carcasses of all animals killed under the Order. We have have sold all flesh passed as sound at an overhead price of 3d. to 3½d. per lb., and it is in great demand.

Besides the usual books for records and returns required by the Board, I keep (a) a Register of cases reported, (b) a Veterinary Expenses Record, which enables us to keep account of the cost of administration in each case, and (c), a salvage and cost of slaughtering record, and my assistant keeps a special book in which the history of cases is related, giving prominence to features of unusual professional interest.

I have with me some of our stationery and a copy of four statements to show the results in detail of working the Order in Lanarkshire during the month of May.

I have not yet under this Order had to deal with any notification that a certain herd was supplying tuberculous milk. Such a case I would deal with by a process of negation, dividing up the animals, examining milk

samples, and so narrowing the issue till the culprit or culprits were found.

We have had two cases of cows that died in transit to the abattoir, and one that died after negotiations were completed but before the carcass was removed. Strictly speaking, compensation is not payable in these cases. What is meant by the word "premises" is a point that mainly concerns the accuracy of returns in which the number of animals in the premises and the number examined require to be stated.

As yet we have done very little inspection of markets in Lanarkshire for the detection of tuberculous animals, but we have now begun this work in earnest. When the days shorten a little we will resume our usual inspection of farm dairy animals, and this will assuredly bring to light a crop of cases to be dealt with under the Order.

Finally, let me say that in assessing the total value of this Order to the stock-owning community and the consumers of milk, no estimate would be complete that did not take into account the effect which its operation will have in educating the people in the subject of disease prevention, cleanliness, etc.

The effects of the Order cannot fail to be beneficial, and it is my view that experience will certainly prove the soundness of the judgment and foresight of the Board.

RESOLUTIONS.

At the suggestion of Mr. Spenser I have drawn up the following resolutions which I now submit for your approval.

1. That this meeting of Veterinary Inspectors, recognising the great practical value of Tuberculin as a diagnostic agent in operating the Tuberculosis Order, regard the present indiscriminate and sometimes fraudulent use of it by unqualified persons as inimical to the proper working of the Order, and agree to represent that the power to possess or use it by unprofessional persons be prohibited.
2. That a copy of this resolution be sent to the Board of Agriculture, the Local Government Board, and the Royal College of Veterinary Surgeons.

Mr. J. CROWHURST said he took especial interest in the matter, because at the last meeting of the Association he put the question to Sir Stewart Stockman whether he could recommend the Board of Agriculture to pass some measure whereby the use of tuberculin should not be in the hands of dealers and owners of stock to be used indiscriminately. His clients were too valuable to him for him to suggest that they would use tuberculin with the object of fraud, but there were people in the world who would use it with such an object, and, in his opinion, it was undesirable that tuberculin should be in their hands. It took away from the inspector the opportunity of arriving at a just and correct conclusion. It had been suggested by the President that Sir Stewart Stockman had been ill, and that might account for the reason that nothing more had been heard about that measure. He had great pleasure in supporting Mr. Begg's proposition, because he believed it would bring the notice of the Board of Agriculture the fact that it was not desirable that tuberculin should be used by the owners of stock. He understood that tuberculin could be obtained from Germany for about 3d. a dose, and he thought the members would agree with him that it could not be reliable at such a price. It might, however, have the effect of frustrating the inspector's investigations.

Mr. F. L. GOOCH enquired whether it would not be desirable to put an addendum to the resolution saying that all tuberculin should be standardised.

Mr. J. CAMERON asked whether it would not be a good thing if the Board of Agriculture were asked to pay the costs—or to reduce the cost say by one half—

of testing the animals of any farmer who wanted his animals tested. That would do away with the temptation to remove them to another place.

Mr. G. P. MALE said he had pleasure in supporting Mr. Begg's resolution, as it was on very much the same lines as the resolution he hoped to propose at the forthcoming National meeting. In his district various persons were going round applying the tuberculin test at a very cheap rate and were thus defeating the objects of the Order. He did not think anybody intended to restrict the sale of tuberculin from abroad, such as the Pasteur tuberculin or any other tuberculin, but he thought there should be some restriction on the sale of it.

Mr. R. BARRON said that Dr. Cobbett of Cambridge had told him that one could test cattle with tuberculin every two days and get a reaction. That news had surprised him considerably. If that were the fact, the people to whom Mr. Male had referred could be defeated if the cow was kept for forty-eight hours before testing. If they had tested the cow beforehand, they could not defeat the Inspector. That was a very practical point.

Mr. D. PUGH desired to draw the members' attention to an experiment which he thought might interest them. At his instigation Mr. Robert Mond bought four tuberculous cows. They were small Jersey cows. He desired to know what would be the effect of a continuous injection of tuberculin. The cows were injected, and a definite reaction obtained, which was recorded in the office. The injection was increased by 3 c.c. every day, and by the time 12 c.c. were reached, three of the animals ceased to react. The fourth continued to react, although he should not call it a definite reaction, because the temperature at the end of every twenty-four hours did not come actually to normal; but he wanted to see what the effect of the continued inoculation would be, and he kept on until the animal was inoculated with 69 c.c., when she got so poor that he decided to have her killed. It was found that every organ in that cow's body was infected with tuberculosis. The other three animals which ceased to react with 12 c.c. were allowed to rest for a month and were again injected with 3 c.c. He then gave them 12 c.c., which was the dose at which they ceased to react, and one of them gave a definite reaction with 12 c.c. Last week he had put the animals through the same process again; he injected them with 3 c.c. and then with 12 c.c., and now they had ceased to react entirely. He had not done sufficient with them to say whether there was a cure, or whether it was merely toleration, but in his opinion it was a cure. He would have to wait and keep testing the animals and ultimately have them destroyed.

Then he had four Shorthorn cows, which were inoculated every fortnight. After a period of time they ceased to react, but one of them had to be inoculated to a tremendous extent before it did cease to react.

He thought the members ought to push forward the motion for all they were worth. It was not the financial point they had to look at; it was the honour of the profession.

The PRESIDENT thought that Mr. Gooch's suggestion as to standardising tuberculin should be put as a separate motion, and he would therefore put Mr. Begg's proposition to the meeting.

The motion was then put and carried.

Mr. GOOCH then moved:—"That in the opinion of this Association the time has arrived when all tuberculin supplied to the veterinary profession should be standardised."

Mr. J. W. BRITTLEBANK seconded the motion. In doing so he said in his experience the standardisation of tuberculin was more called for than the restriction of its sale. It was really ridiculous, if one tried a good many tuberculins, to find how different the results

were. Some tuberculins were absolutely useless, and with regard to others, even in advanced cases, an ordinary normal dose would give a reaction. With regard to what had been said about repeated doses of tuberculin, he was afraid his experience had been that one could use tuberculin as often as one liked, and obtain reactions, but one had to be careful where the tuberculin came from.

Mr. W. R. EMERY suggested to all veterinary surgeons or veterinary inspectors who used tuberculin that they should obtain it from the Royal Veterinary College. His experience of such tuberculin was that it was always efficient, satisfactory, and of standard quality.

The PRESIDENT said it was a personal matter as to where the members obtained their tuberculin.

Mr. T. EATON JONES asked if the motion would not be placing a hardship on tuberculin manufacturers. A practitioner, if he used much tuberculin, would find out whether it was reliable or not. Personally he did not think there would be much use in standardising tuberculin, and it would be imposing a hardship on a good many reliable manufacturers.

The PRESIDENT said there was no doubt that various actions were obtained from various tuberculins, some of which were very misleading. He knew of one case where a gentleman tested some animals with tuberculin which gave no reaction. Another gentleman tested them with a different tuberculin, and obtained a reaction. He did not know how tuberculin was going to be standardised. There were a lot of foreign manufacturers sending tuberculin into this country, but so far as tuberculin manufacturers in this country were concerned, they, at all events, might standardise it. It could do no harm to pass the motion.

Mr. J. F. HEALY said at the late Dublin Show the American buyers tested all the animals with Pasteur's tuberculin. The matter ought to be considered before the motion was passed, because the South American buyers would not have any tuberculin other than Pasteur's.

Mr. F. L. GOOCH said he had had to test 15 bulls for the South American trade, and they were all tested with M'Fadyean's tuberculin.

Mr. H. G. LEPPER said there were times when tuberculin of a higher standard was required than at other times. That was a point to be considered.

Mr. T. EATON-JONES proposed that the motion lay on the table for twelve months.

A MEMBER said that before the resolution was passed it ought to be found out whether tuberculin could be standardised or not.

Mr. J. W. BRITTLEBANK said it was perfectly feasible to standardise all such products. It was well known to bacteriologists and chemists that all such products were capable of being made of equal value. It did not matter, he thought, whether tuberculin was sold by different people so long as veterinary surgeons obtained a really good and potent tuberculin. If a dose of one tuberculin was twice as potent to produce a reaction as a dose of a similar tuberculin sold by somebody else, where were they in practice? Mr. Jones had said that one could use a tuberculin which one found best suited to one's practice. That was all very well, but possibly the beast was tested again by somebody else and there was a negative result. He did not think there was any serious difficulty in the way at all. The indiscriminate sale of tuberculin without any value should be put a stop to, that was what it came to.

Mr. J. DUNSTAN rose to support Mr. Gooch's motion. Undoubtedly tuberculin could be standardised, and he thought it would be well for every member of the profession to know the strength or the value of the tuberculin which he was using. They were not all in the position of Mr. Jones to be able to test animals and to follow them to the slaughterhouse within a few days

and to form an opinion on the value of the various tuberculins, especially in remote country districts. Therefore he thought if a substance of standard value could be obtained, it certainly would be of the greatest possible assistance, to country practitioners especially.

Mr. J. CROWHURST said there were well known instances where animals had been tested in this country for exportation which had not reacted, but on being tested abroad did react. Either it might have been that the tuberculin on this side was not reliable, or the tuberculin on the other side was not.

The motion was then put and carried, Mr. Jones withdrawing his amendment.

Mr. E. L. DIXON desired on behalf of himself and the other members to thank Mr. Hugh Begg for his very able paper, which was full of valuable instruction. With regard to the working of the Tuberculosis Order, he had had nine cases since it had come into force dealing mainly with regard to the utilisation of the flesh for food. He was veterinary inspector to two health resorts, and his Sanitary Committees took exception to the use of the flesh of tuberculous animals as food in any form. They put it to him plainly, Did he recommend, as a veterinary surgeon, that the flesh of an animal which he had condemned for tuberculosis should be used for human consumption? He had replied, "Well, gentlemen, you cannot go outside the four corners of the Act. It permits you to use the flesh under certain conditions. It depends entirely upon the post-mortem. The valuation is either three-fourths or one-fourth, according to the result of the post-mortem." But they would not listen to him, and rather than run any risk, they had paid the three-fourths compensation instead of the one-fourth. He thought all the members were indebted to Prof. M'Fadyean for holding his classes, so that they might improve their knowledge on the matter. (Hear, hear.)

Mr. BANHAM enquired of Mr. Dixon whether his sanitary authorities worked the Diseases of Animals Act in his districts.

Mr. DIXON replied in the affirmative.

Mr. J. CAMERON said although the members were thankful to the Board of Agriculture for inaugurating the Order, and for going as far as they had done, yet they had not gone so far as it was expected they would do, or should do. Of course the authorities could not go further than their funds would allow them, and unless the profession continually made complaints on the subject, how could they expect Mr. Runciman to be able to influence the Treasury? If there were no complaints the natural thing for the Treasury to ask was, "What evidence is there that the Order is not satisfactory and that you have not enough money?" It was the profession's duty to supply that evidence, and to support the conclusions to which Mr. Begg had come, that although they were thankful for what had been done, yet still more was required to be performed.

Mr. R. BARRON said Mr. Begg was not in the unhappy position that many of his colleagues were, of having to struggle in general practice for a living, and therefore he did not deal with the question of fees quite so adequately as he (Mr. Barron) would have liked. His (Mr. Barron's) idea about the Association was that the members should unite together in order to get reasonable fees out of the County Councils. He should like to cite the case of his own County Council in Dorset. Mr. Toope advised him to get the veterinary surgeons in the county to put their heads together with him and to organise themselves, and to say that they would not do the work any longer at the current fees. He did so, with the result that after various meetings between the parties the County Council practically conceded most of their demands. His idea about the Association was that one of its functions should be to put one man in

every county to organise his fellow professional men so that they might all stand together. If they did so they were bound to win.

With regard to the working of the Order, what was being done in Dorset by the farmers was that when a cow got a bad udder they said nothing at all about it, but simply removed her out of the dairy. If it was a case of emaciation they reported it, and the veterinary surgeon was allowed to go in. The farmers complained very much about the compensation. For many of their cows which were emaciated they could get £4 to £7. They could put half a dozen of them in a truck, send them to London, and make £6 or £7 a head; whereas they only got 30s. under the Order. They therefore said that the Act was most unfair, and he himself certainly thought that the compensation allowed was not sufficient.

Mr. COLEMAN said in his district, 57 animals had been killed, and up to the present time there had not been a single mistake, and there had been some of the most dreadful cases he had ever come across. In one case the liver weighed 47 lbs., the mediastinal and bronchial lesion in one case was 4½ lbs., and in another 1½ lbs. In his experience it was very difficult to discriminate between emaciation and poorness. His definition of emaciation was when it was poorness resulting from disease and the food was not assimilated. Poorness was the result of the withholding of food or the giving of non-nutritious food. In the early part of the year the hay in his district was absolutely void of nutrition, and it was very risky to differentiate between emaciation and poorness, but fortunately he resorted to the test, and he had not made any mistake. There was a prosecution about to be taken in his district under the Order. The facts were as follows: In the first place the London County Council discovered acid-fast bacilli in the milk coming from animals on a farm in his neighbourhood. The medical officer sent a veterinary inspector down, who discovered that one of the animals was giving tuberculous milk. The medical officer thereupon advised the farmer that he must not send any more milk to London, that he must isolate the beast, and notify the local authority. The farmer notified the local authority to the extent that he employed a local lackerman, who dealt in that class of beast, and who removed it into another district. He (Mr. Coleman) went to see the beast with the deputy Chief Constable on the Saturday, but they were told it had been removed that morning. They followed it to Faringdon, and gave instructions that it was not to be dealt with until further orders. He then went to the Superintendent of Malmesbury and handed the beast over to him. On post-mortem, tubercles about as big as mustard seeds were found. The authorities were prosecuting at his end, and were going to suggest that the man who put it with the other beasts should also be prosecuted at that end. In conclusion, he might say that the farmers in his district were withholding the reporting of their cattle on account of inadequate compensation.

Mr. G. WARTNABY said so far as his district was concerned, the Order was almost a dead letter. The County Council was diametrically opposed to the Order. The Council had fixed the fees of veterinary inspectors, who had been told, "These are the fees which we are going to give you. If you do not like to accept them, say so, and we will put somebody else in your place, or we shall appoint an all-time man." Did the members think that there was a man in the district who, knowing that, was going to report a cow with an indurated udder? If a man found such an udder he would say it had been trodden upon. He would like to give the members an example of a case of tuberculosis with emaciation. A case was reported to the police about three weeks or a month ago. He visited the beast in the field, and he found a very bad case of emaciation.

In looking over the other beasts he found another case. He ordered the two beasts to be slaughtered, but on the way to the slaughterhouse one of them died. He only mentioned that to show the condition that the animals were in. They were not reported by the owner, and would not have been, had it not been that an outside man reported the case to the superintendent of the police. He would like to know the exact definition of the word "premises." Was a field with 30 or 40 beasts in it to be considered as "premises"? Was the whole farm to be considered as "premises"? The instructions of his County Council were "You must not examine any other beast except the one which is reported to you, unless you have reason to suspect that it is tuberculous." How was one going to suspect that the beast was tuberculous without going and looking through the lot? In the first case he had, he said to the police: "Telephone to the county and ask what is to be done. Here is a tuberculous beast amongst 32 others in a field." The answer came back "Examine the other beasts." When he sent his bill in, it was returned with a marginal note, "Please say on what ground you have charged such and such an amount, and where you got your instructions. We refuse to pay you." He replied that he had received his instructions from the Chief Constable's office, and his claim was allowed.

Mr. SYDNEY VILLAR asked if it was the experience of the members that animals in ill-health were likely to abort from injections of tuberculin, and whether the reaction to tuberculin in a sick animal was ever likely to be so great as to kill it.

Mr. COLEMAN said he had within the last month tested 20 cows within two months of calving, and not one of them had either aborted or showed any bad signs.

A MEMBER asked if there was any rule in regard to the period at which authorities, outside the authority of which one was veterinary inspector, should give notification that a suspected case had occurred in the locality. In his first case under the Order he received information and hurried to a farm for a suspected case, only to find that the beast had been removed six weeks previously. A mixed sample of milk from the farm had been sent to London, examined, and found tuberculous. The veterinary inspector of the London authority had come down, examined the herd, and found one animal whom he suspected to be giving tuberculous milk. He took a sample from the animal back to London, where it was no doubt physiologically tested with guinea-pigs, and found to be tuberculous. Then a notice was sent down to his (the speaker's) local authority to say that the cow was giving tuberculous milk. He thereupon went to the owner and asked where the animal was. The owner replied that it had gone. He enquired of the owner why it had gone, as it was a suspected animal. The owner replied "The inspector came down and said it was the one he suspected. I asked him what I should do. He said 'I should get rid of it as soon as you can,' and consequently the animal went straight off to the dealers, and it has not been since traced. Ought not the outside authority to notify at once the local authority of the district in which the cow was?"

The PRESIDENT, interposing, said the Act ordered that that should be done.

The MEMBER, continuing, said in the particular case he was describing, six weeks elapsed before any information was forwarded to his local authority. With regard to the disposal of carcasses, his Council took an exactly opposite view to Mr. Dixon's councils; they were extremely keen on getting all they possibly could out of the carcasses. He thought it placed the veterinary surgeon in rather an invidious position, having to try to palm off, to the very best advantage they could, meat, parts of which, at any rate, were diseased.

Mr. PITTS said one difficulty he had found was to obtain suitable places in which to slaughter the animals. Mr. Begg was in the happy position of having abattoirs supplied to him. In his (the speaker's) county the butchers would not have any of the animals near their places. The result was that he was in a very awkward position. He could not go to the adjoining farmer and ask his permission to bring a tuberculous animal on to his place and slaughter it. At present he was supplied with hampers in which to pack up what bits of the carcase were good, and send them up to the London market, but he must say that that method did not appeal to him.

Mr. CROWHURST said that in his county he sent all the meat he could to the hound kennels.

Mr. KING asked Mr. Begg in what proportion of the cows he had examined for tuberculosis of the udder, he had found the supramammary glands affected, and whether, if he had found them enlarged, he had verified they were tuberculous from post-mortem examination?

Mr. G. P. MALE said it might interest the members if he gave one or two statistics which had been prepared by the Board of Agriculture in answer to a question in the House as to the working of the Order. They were the statistics up to the 22nd July. There had been 1559 animals destroyed. On an average five cows had been examined on each premises. Very few mistakes indeed had been made by veterinary surgeons in their diagnoses. The majority of the cows were suffering from advanced tuberculosis. The average compensation given was £2. Those figures showed that most of the animals were in a very advanced stage, and probably most of them were emaciated. He quite agreed with Mr. Begg that the weakness of the Order was the clinically affected cow which was not sufficiently thin to be called emaciated, but which was a dangerous cow, and one emitting numbers of tubercle bacilli. Under the Order, a practitioner had to wait till the cow got emaciated before he could deal with it. He hoped as time went on, the Board would see its way to extend the regulations to include those cows which were clinically affected, which were coughing, say, or emitting discharges, or which had any other clinical symptoms of tuberculosis other than tuberculosis of the udder, and which were not sufficiently thin to be called emaciated. He thought that would be a very great step towards checking tuberculosis amongst the herds of this country.

Mr. W. R. EMERY said there was one point which he had noticed in connection with the animals coming into the market of which he was the inspector. Sometimes fat animals came in, were sold, taken to the butcher's, and there found diseased. How could a market inspector guide himself as to whether an animal in the market which appeared to be in tip-top health had tuberculosis or not? It was only after death that that was found out. He manipulated the udders of a great many cows each market day, and unless he found they had some induration, separate and distinct from any other part of the udder he came to the conclusion that they were tuberculous cows.

Mr. BRITTLEBANK joined in the general congratulations which had been offered to Mr. Begg on the character of the paper which he had given the members. There was no doubt about it that much of Mr. Begg's material had been so presented as to be of the very greatest possible value. Mr. Begg had handed him a table which showed how very thoroughly the whole of the Order had been administered in the County of Lanark. It was very gratifying to see there were some counties which had made up their minds to carry out the Order in some proper sort of spirit. So far as the area in which he himself worked was concerned, they seemed to be going through a period of intense excitement and resentment. He had been brought pretty

intimately into contact with the administration of the Order in several counties. The most prominent features which he had found seemed to be that the local authorities congratulated themselves that the Order was working beautifully, and their machinery was so well oiled that absolutely nothing could throw it out of gear. Taking one county, the way in which the Order had been administered up to the present time—he did not know for what reason; possibly for lack of administrative staff—had been one of the greatest shames he had known. A great many cows had been notified to the local authorities, and in many cases as long as a month elapsed before the cows were finally disposed of. Mr. Begg had very sensibly drawn attention to the awful agony which a cow went through during its period of isolation. In the case of the county he had mentioned he knew of two cases where the animals had died in their isolation surroundings whilst waiting for slaughter. Another point was that the interference of the police was very much resented. One particular individual with whom he had discussed the matter had told him that after notifying a case he had had three police constables, two sergeants, two superintendents, the deputy chief constable, the chief constable, and two other individuals whom he did not know, at his farm. The man further added: "The end of it all is that my poor wretched cow is fastened up in a loose box by herself and she is pining away and will be dead before many days are over." The animal when he (Mr. Brittlebank) saw her in the first instance was certainly not an emaciated cow but in good condition. The man received no compensation at all, because after a period of a month she died, and there was no attempt made to carry out the slaughter. It seemed to him that if a good deal of the police interference could be done away with the Order would work very much more smoothly. People who had to be dealt with under the Tuberculosis or any other Order, had committed no offence, and there was no earthly reason why they should not be treated in a sympathetic manner and helped as much as possible to get their stocks into decent condition. In his experience of the average dairy farmer the backslider was very distinctly in the minority. As years went on he was certain there would be found an enormous development of the desire to progress. Mr. Begg rather regretted that cows suffering from tuberculosis of the lungs, other than emaciated cows, were not brought within the purview of the Order. All the members regretted that, but Mr. Begg went on to say that the compensation on the quarter rate would not be serious. He (Mr. Brittlebank) was prepared to admit that from the county point of view it might not be serious, but he was also prepared to say that the opposition from the dairy farmer's point of view would be very considerable. There was not an ordinary untested dairy stock in the country which did not have two or three cows suffering from tuberculosis of the lungs, and very often such cows were as fat as working dairy cows would be. He thought before the Board could advance on such a policy as laid down by Mr. Begg, however desirable it might be, they would have very serious opposition to contend with, and they would have to very seriously amend the scale of compensation. Another point to which Mr. Begg referred was as to which particular portion of the milk contained most tubercle bacilli. That was a matter of some considerable importance. From an administrative point of view and from a practical point of view it was of the very highest importance to the veterinary inspector. Prof. Delépine had carried out a very considerable number of experiments; the whole of his work on the examination of milk stood out for its accuracy, and there was no question of doubt about it that from their experience they found that the last milk which was contained in the udder, plus any more that could be squeezed out by a process of massage.

contained most bacilli, at any rate in their district. Perhaps Mr. Begg's suggestion of Scotch bacilli containing a high degree of intelligence and armed with fish hooks might be a solution of the difficulty, but he hoped that those bacilli would stop in Scotland. His idea was not with regard to finding any intelligent bacilli, but rather the fact that if careful post-mortems and careful examinations of tuberculous udders were made, and the milk ducts were followed up as far as was possible, very often it would be found that the animal was suffering from a tuberculous ulceration of the mucous membrane of the duct; and it had always struck him that if some of the material which was lying at the bottom of the ulcerated portion could only be squeezed out, one would then get a material highly charged with tubercle bacilli.

Mr. Begg said that he had seen no case of a tuberculous quarter where one could not get any discharge or secretion. He (Mr. Brittlebank) admitted that that was true in the majority of cases, but he had had a few cases in the course of his experience where it was absolutely impossible to draw anything at all, and where it was also impossible to pass a teat tube. Such cases had been dealt with in the past on the clinical evidence presented. One might also employ the tuberculin test in such cases. It would never tell one whether the animal had a tuberculous udder or not, but it was a safeguard to some extent. With regard to the point raised by Mr. Villar about cows aborting during the testing with tuberculin, his experience had been that one need fear no untoward results at all from the administration of tuberculin. He would just describe a case of the effects of tuberculin in a herd that he had tested some little while ago. In a certain herd in an adjoining county, he was of opinion that there was such a high percentage of tuberculous animals that it was an extremely dangerous herd from which to admit the milk for sale. An Order was therefore made on the farmer restraining him from supplying any more milk to the City of Manchester. The farmer placed his case before the Committee accompanied by representatives of various Associations, and the Committee asked him (Mr. Brittlebank) whether he was prepared to withdraw his opinion. He replied emphatically in the negative, and said that in his opinion the herd was grossly infected, and if the milk was accepted he would not take the responsibility. To cut a long story short, the owner said he would accept the verdict of the tuberculin test as to whether his herd was highly infected or not. In conjunction with a local practitioner, therefore, he tested 49 cows, and there were 47 reactions. The curious part of the case was that on the following morning, eight hours after the inoculation, 22 of the cows were laid out full length in the cowsheds groaning in a most alarming manner. The farmer said they were on the point of death, but they all got better by night. He never saw anything so violent in the way of reactions in his life. He would have, before he had had so much experience, been perfectly prepared for two or three deaths to have occurred, but inside 24 hours the herd had regained the normal state. An interesting point brought out in the testing was as follows. Several of the cows were killed; the farmer and himself became firm friends, and it was agreed that when the cows were killed he should see them slaughtered. He tested several of them several times, and he placed it on record that he had yet to find a cow suffering from advanced tuberculosis that would not react to tuberculin. There was one particular cow which had become a noted animal in the reports made to the Local Government Board. She was tested with tuberculin in the most advanced stages, and she reacted, and reacted early; and when the post-mortem was made, he did not think it would have been possible to have placed a sixpence on any piece of healthy tissue throughout the

whole serous chain from head to tail. That had been his repeated experience. But the tuberculin had to be a potent tuberculin. If there was any doubt about it, his practice had been never to hesitate to give a double dose. If he had any suspicion of faking, he always gave as much as 7 c.c. of tuberculin instead of 3 or 3½ as the case might be.

Mr. HUGH BEGG, in reply, said he was exceedingly gratified at the very gracious way in which the various speakers had given voice to their ideas. He had been rather hoping that the members would have stopped talking so much about tuberculin and have got on to their experiences, but probably those would come out at future meetings. With regard to the point upon which Mr. BRITTLEBANK and he were in opposition, namely, what portion of milk contained most tubercle bacilli; he supposed the members would be all of the opinion that when one went to milk a cow, her bag had not a quarter of the milk in it that was eventually obtained. He submitted that a cow secreted far more milk during the process of milking than she secreted at any other hour or two hours during the time from her last milking. On that basis he found some probable solution of the discrepancy which existed between Mr. BRITTLEBANK's suggestion and the actual experiments that he himself had conducted. Mr. BRITTLEBANK did not say he had conducted experiments—

Mr. BRITTLEBANK, interposing, said the experiments were conducted by Prof. Delépine.

Mr. BEGG enquired if Prof. Delépine had made specific counts.

Mr. BRITTLEBANK replied in the negative, as far as he knew.

Mr. BEGG said that was the point he wished to make. He submitted that a cow secreted more milk during the process of milking than at any other time, and that probably the last milk was the fresher milk and was not in contact with tuberculous tissue.

Mr. BRITTLEBANK had also said that he had yet to find a cow suffering from advanced tuberculosis that would not react to tuberculin. He must differ from Mr. BRITTLEBANK there, because he had had at least four cows under the new Tuberculosis Order—and he thought he could mention many others—in regard to which he had reported in his preliminary report that the tuberculin test was not reliable. Mr. BRITTLEBANK had referred to the case of a certain county as carrying out the Order very badly, and had mentioned a certain cow having

died in four weeks because a month had elapsed before the disposal. He (Mr. BEGG) thought if the borders of the Order were extended so as to include phthisical patients, coughing up tubercle bacilli, many of those cases would be killed on the spot. He did not at all understand the point about the interference of the police. He could not understand that matter at all. In his county no police went near the cases. When a cow was killed, and he had reason to suspect from the character of the man that he would pay no attention to the notice to disinfect, he might ask the superintendent of the police to tell his sergeant to call there when he was passing to see that there was disinfection.

Mr. TREVOR SPENCER enquired who served the notice of detention in the first instance.

Mr. BEGG replied that he himself did everything in connection with the matter.

Mr. MALE enquired if Mr. BEGG disposed of the carcass himself.

Mr. BEGG replied he always disposed of the carcasses which the meat inspectors thought worthy of being passed. He was surprised to hear that veterinary surgeons in England were opposed to the passing of certain portions of tuberculous carcasses. Surely they all subscribed to the opinions expressed by the Royal Commission. Did any veterinary inspector present mean to say that in the case of localised lesions of tubercle, the whole carcass ought to be condemned?

Mr. MALE asked if Mr. BEGG took the responsibility of selling it, or if he left the responsibility to the local authority.

Mr. BEGG replied that the local authority was responsible for anything he did. It seemed to him that the veterinary profession had the success of the Order in their own hands. If they were going to stand still and not impress it on their local authorities, then the local authorities would take up the attitude of the veterinary inspectors. In the counties where the local authorities were averse to the Order, it was because they had been advised by the veterinary inspector that it was an Order to be averse to. If the Order was not a thing which the profession had been praying for for the last fifteen years, then he was a Dutchman, and if they did not go on and make the Order a success they ought to hide their heads for evermore.

Mr. DUNSTAN then moved a very hearty vote of thanks to the President for his able Presidential address.

Mr. J. CAMERON seconded the motion, which was carried with acclamation. The President returned thanks.

Mr. BRITTLEBANK said he rose with the greatest possible pleasure to move a very hearty vote of thanks to Mr. Begg for attending and opening the discussion on the Tuberculosis Order, and for putting before the members in such a practical manner the whole of his experience.

Mr. GOOCH, in seconding the motion, said Mr. Begg's contribution was hardly an opening of a discussion, it was an elaborate paper upon the practical issues of the Order, and he thought it ought to be named such in the report.

The motion was then put and carried with acclamation. The meeting then terminated.

TREVOR F. SPENCER, Hon. Sec.

Tuberculosis Order, 1913.—Prosecutions.

In the Sheriff Court on 31st July, William John Kerr, cattle dealer, Forfar, appeared on a charge of having contravened the provisions of the Tuberculosis Order (1913) and the Diseases of Animals Act (1894) by having had in his possession, from July 12th to 14th, a cow which was or appeared to be suffering from tuberculosis, of which he failed to inform the police.

The Procurator-Fiscal said that the animal originally belonged to a Kingsmuir man, who gave it away to a local drover to put out of the way, and the latter sold

it to accused for the sum of 10s. When the question of compensation came up after the animal was condemned, Kerr asked the price of £10. Eventually he agreed to take £3, but owing to the advanced state of the disease was only entitled to 30s., which was the minimum compensation. He thought it a case for a smart penalty.

Mr. J. W. Lowson appeared on accused's behalf and stated that accused knew that the cow had been treated for an affection of the throat and had no reason to suppose that the emaciation was due to tuberculosis.

Sheriff Taylor imposed a penalty of £2, with the option of fourteen days' imprisonment.

On Tuesday, Aug. 12th, at Swindon, a Hannington Wick (Wilts) farmer named Russell was fined 30s. for failing to notify that one of his cows suffered from tuberculosis of the udder.

The deputy chief constable said in consequence of tuberculous milk having been received in London, an inspector examined the herd, and defendant was told that he was bound to report the case to the local authority. This was not done, and on July 12 the cow was sold by him. The police traced the animal to a farm at Great Coxwell, in Berkshire. When told he should have reported the matter defendant replied, "Oh, I don't trouble about the Tuberculosis Order, that is all rot. You can do as you like."

Mr. Alexander Dunbar, M.R.C.V.S., a London County Council inspector, said that certain milk which was sent to London was discovered to contain suspended tuberculosis matter, and the contaminated liquid was traced to defendant's farm.

Serum Treatment of Swine Fever.

At the last meeting of the Council of the Royal Agricultural Society, Mr. Mansell said he would like to raise the question of the Society urging on the Board of Agriculture the importance of trying the serum treatment with reference to swine fever. Experiments had been made in Holland, Norway, and other countries, and he believed with considerable success. Seeing that they were making no headway, and were spending enormous sums of money in this country, he thought the Board of Agriculture should be urged to take steps to try the serum treatment.

Mr. Stanier inquired whether Sir John M'Fadyean had gone into the question, or whether he might be asked to do so on behalf of the Society.

Sir John M'Fadyean said he was very well acquainted with the use of serum in the treatment of swine fever, as he had endeavoured to keep himself posted regarding that method of treatment since it was first introduced into the United States a few years ago. He was also pretty fully acquainted with the use of the method in Holland, and with that knowledge he would be very sorry to press upon the Board of Agriculture that they should test the use of serum. The expression was, of course, very vague, but, as he understood it, the recommendation would be that the Board of Agriculture should imitate Holland, where he believed there were no restrictions whatever with regard to swine fever. The person who had swine fever on his premises in Holland could disperse the pigs and spread the disease to twenty other owners. It was all very well to say that each of those owners could considerably reduce his losses by employing serum, but he thought it was well the Council should know that, as an alternative to the method of endeavouring to control and eradicate swine fever, the use of serum could not, in his opinion, be recommended.—*Farm and Home*.

It is of interest to know that on behalf of the largest pig feeders in England, Mr. G. H. Kitchin, M.R.C.V.S., Harrow, has been to Rotterdam to investigate the new serum treatment for swine fever carried on there. We understand he is greatly impressed with the utility of it, and is at present in communication with the Board of Agriculture with a view to its introduction into this country. As swine fever is very prevalent in the Harrow district, a treatment for the prevention and cure of it would be of the greatest importance.—*Meat Trades' Journal*.

Action for Loss of a Mare—Contagion.

At the Ashbourne, Derbyshire, County Court on the 6th inst., before His Honour Judge Alan Macpherson, Richard Howe, farmer, of Fenny Bentley, claimed £20 17s. 6d. from John Edge, farmer, of Kieve-ton, for the loss of a mare, such loss being attributed to the defendant's negligence. Mr. A. Brett supported the claim, and Mr. E. A. Wilkins was for the defence.

Mr. Brett said the defendant owned a stud of horses, and on June 16th one of the stallions served the plaintiff's mare. On the following day the latter animal was noticed to be listless and off its food, and on the 18th Mr. Duckworth, veterinary surgeon, was sent for, and he treated the mare, but she died on the 21st of the same month. A post-mortem was arranged for the 22nd, and defendant was notified of the fact, but he did not attend. Mr. Edge, said Mr. Brett, had previously admitted that this particular stallion was in an unfit condition, and three days before the service he obtained some lotion for it. The loss of the mare was a serious matter for plaintiff, who was a smaller farmer than the defendant, and plaintiff's harvest was delayed.

Mr. T. H. L. Duckworth, M.R.C.V.S., of Ashbourne, described the nature of the disease from which the mare died (septic gonorrhœa), and said the autopsy bore out the diagnosis he had formed. He valued the mare at from £15 to £17.

In reply to Mr. Wilkins, witness said the symptoms of unfitness in the horse would be apparent to the owner.

The plaintiff bore out the details mentioned in Mr. Brett's statement, and said he bought the mare in 1910 for £15, but she was then in poor condition. Defendant told him that there was nothing the matter with the horse, but added that if he had been at home at the time the mare was taken to his farm he would not have allowed it to be served by the stallion. The mare had had two foals since he purchased her, and was worth more than £20 to him.

Richard Howe, jun., stated that he was present at the time of service, when the defendant's horse appeared to him to be all right.

Reginald Salt, of Fenny Bentley, deposed to hearing a conversation between plaintiff and defendant, in the course of which Mr. Edge said there was something the matter with the horse, and plaintiff asked why some medicine had been obtained for it.

In answer to Mr. Wilkins, witness said Mr. Edge did not say that the stallion could be examined.

The defendant was then called, and said he valued the mare at £10. The stallion was all right beyond having sustained a scratch, and this was perfectly clean when the mare was served.

Ralph Warrington, groom, formerly in the employ of Mr. Edge, deposed that the injury to the horse as described by the defendant.

Joseph Dakin, George Etches, John William Wigby, and John Wright spoke to having seen the horse in question, and said it showed no symptoms of disease.

Mr. J. C. Deville, veterinary surgeon, of Uttoxeter, stated that if the horse had had the disease which was alleged, the owner must have been aware of the fact.

Addressing His Honour for the defence, Mr. Wilkins said his client, to be made liable, must have known the horse was unfit for service.

His Honour, in giving judgment, said he was told that the plaintiff had succeeded in establishing the fact that the cause of the mare's death was a result of the service by defendant's horse, and he had not the least doubt that defendant knew, or strongly suspected, that there was something wrong with the stallion before the mare went to be served. That being so, there must be a verdict for the plaintiff.

His Honour then gave judgment for £17 with costs.

The hearing lasted until well into the afternoon, and a large number of farmers and dealers followed the evidence with much interest.

Inspectors of Live Stock.

The President of the Board of Agriculture and Fisheries proposes to appoint two inspectors in connection with the administration of the Board's scheme for the improvement of live stock.

The salaries, exclusive of travelling expenses, will be one of £500 and one of £600 a year, rising in each case by annual increments of £20 to a maximum of £700. Applicants must possess a thorough practical knowledge of stock-breeding.

Applications should be addressed to the Secretary, Board of Agriculture and Fisheries, 3 St. James' Square, S.W., from whom forms can be obtained, and should reach the office of the Board not later than August 18. It is unnecessary for those persons who have already communicated with the Board to renew their applications.—*The Times*.

Vivisection and Veterinary Science.*To the Editor of the Times.*

Sir,—According to the report which appeared in *The Times* of Friday, 8th inst, Professor Harvey Cushing, in the course of an address which he delivered on the previous day to the members of the Congress of Medicine, made the statement that, "Most veterinarians have profited not at all by the advance in general medical knowledge of the past generation," and exclaimed that "It was little wonder that people preferred to have their pets, when in need of surgical care, operated upon in an experimental laboratory rather than in many of the established veterinary hospitals." I hope you will allow me to enter an indignant protest against the public affront which was thus put upon the veterinary profession. Even if it had been true that the majority of veterinary surgeons of the present day are as ignorant as Professor Cushing asserts them to be, the fact would not have furnished any argument in favour of the practice of vivisection with a view to the advancement of medical knowledge. But, Sir, the statement is grotesquely untrue, and it therefore deserves to be denounced as a wanton libel. Professor Cushing is an eminent surgeon, but the references to animal diseases which are contained in his address prove that he does not possess the knowledge which would justify him in sitting in judgment on the present state of veterinary science. With your permission, I will challenge him to bring in support of the view expressed in the sentence quoted above the opinion of any surgeon, physician, or pathologist whose name carries weight in Europe.

The suggestion that people in general prefer to have their pets operated upon by human surgeons needs no refutation. Perhaps, however, Professor Cushing only meant that that was the state of things in Baltimore.—I am, etc.,

J. M'FADYEAN.

Royal Veterinary College, Aug. 9.

Veterinary Inspectors' Fees in Wales

Previous to the last meeting of the Public Health and General Purposes Committee of Carmarthenshire County Council, a private meeting of the veterinary inspectors of the county was held at the Boar's Head Hotel, Carmarthen, when a scale of charges for working the Tuberculosis Order was decided upon. There were present Messrs. J. Campbell Hill, Llanelly; J. F. Rees, Carmarthen; E. Phillio Jenkins, Llandilo; J. Jones, Newcastle Emllyn; T. Williams, Whitland; and Mr. Harries, Pencader.

The scale agreed upon was: First visit, 1/- a mile one way and 7/6 inspection; Tuberculin test 2 guineas up to four animals; Post-mortem examination 10/6; Attendance at fair or market 10/6 for three hours.

This was afterwards submitted to the Public Health Committee and agreed to by them, subject to the approval of the County Council.

Condition of Prince Palatine.

The Press Association is requested by Captain H. B. Purefoy, of Pounds Farm, Lambourn, Berkshire, to publish the following statement by Mr. G. E. King, M.R.C.V.S., who is attending Prince Palatine:—

I certify that I have made an examination of Prince Palatine at Pounds Farm at the request of Captain Purefoy. I find there is distinct evidence of a severe blow upon the near foreleg, which causes lameness. I have further made a careful examination of the horse's heart and other organs and find no suspicion of any disease or trouble whatever.

GEO. EDW. KING, M.R.C.V.S.

The Vineyard, Abingdon, Aug. 2.

MESSRS. NEWTON, CHAMBERS, AND CO'S "IZAL" PUBLICATIONS.

We have received four booklets issued by Messrs. Newton, Chambers, and Co., The Laboratories, Thorncliffe, near Sheffield, manufacturers of the well-known "Izal" disinfectant. The two largest are entitled respectively "The Izal Veterinary Handbook" and "Healthy Poultry"; the third is an account of the uses and value of Izal in the prevention of rinderpest, foot-and-mouth disease, and anthrax; and the fourth deals with "Izal in the Dairy." All will be useful to stock-owners, especially perhaps the two last, which are mainly concerned with the methods of disinfecting buildings, utensils, etc., with Izal, and the second, which also contains some useful elementary general information regarding poultry.

The "Veterinary Handbook," like all such publications, is to a certain extent open to the objection of encouraging veterinary treatment by laymen, but is much less so than some similar works we have seen. It will do much more good than harm, and will be especially useful in showing owners how to limit the spread of infectious diseases. There are, of course, a great many disinfectants in the market, not all of which are of proved value. Izal is one of those the efficacy of which has been proved both in the laboratory and by the test of practical experience; and these booklets, which explain in detail the methods of its employment are bound to be useful.

ROBERTS.—On Aug. 14th at Beaufort Square, Chesham, the wife of Arnold E. Roberts, M.R.C.V.S., of a daughter.

MR. PANTON, M.R.C.V.S., of Blair Athol, was judging the Highland Pony Classes at the Show of the Perthshire Agricultural Society, on the 2nd inst.

MR. D. MACFARLANE, M.R.C.V.S., Doune, judged the Hackney Class at the Strathearn Agricultural Society Show at Crieff, on Tuesday, 5th inst.

MR. ALEX. JOHNSTON, M.R.C.V.S., Blackbog, Fyvie, obtained a "First" with a Clydesdale mare, at the Garioch Club Show at Insch. on 2nd inst.

MR. R. BRYDON, M.R.C.V.S., Seaham Harbour, obtained eight firsts and eight seconds, chiefly with foals by Bonnie Buchlyvie at the Durham County Agricultural Society Show, at Sunderland. He was successful in the yearling class, and in the two-year-olds.

OBITUARY

C. J. DUNN, M.R.C.V.S., Upper North Street, Poplar. Graduated, Glas: Dec., 1889.

Mr. Dunn died on Saturday, Aug. 9, at St. Bartholomew's Hospital, from uræmia. Aged 44 years.

The Late Mr. W. Anderson.

Mr. Anderson, whose death at Dumfries, at the age of 73, we regret to announce, resided for many years at Hexham, and was well-known for miles round. He was not a native of Hexham, but soon after passing for his degree at Edinburgh, he commenced practice in the town, and in the course of years established a large professional connection in the extensive agricultural area of which Hexham is the centre. In fine weather and in foul, in summer and in winter, his trap was seldom absent from the highways and byways and occupation roads of the country districts, so that few professional men were better known.

Mr. Anderson possessed in a marked degree the "perferdum ingenium Scotorum," and almost invariably talked the Scottish Doric in conversation with his friends. Perhaps this may account for his love of the bagpipes, which he played at concerts and other entertainments in town and country whenever his services were required for a benevolent or charitable purpose. On several occasions he accompanied the late Dr. Bruce when the latter was lecturing on the Northumberland pipes, his performances being illustrative of the differences between the two instruments. He was one of the founders of the Hexham Burns Club, a popular local institution in Hexham for many years. Both English and Scottish admirers of the bard were wont to foregather on the 25th of January, in the Royal Hotel, where the dishes, provided by a Scot, always included the "chieftain of the puddin' race." Sometimes, at these dinners, he would sing a Scots song, occasionally a Latin lyric of his student days, and almost invariably he would play a few tunes on his pipes. Modest and unaffected in his manner, he was a man of strong convictions on some things, and when he had once taken up a mental attitude towards a question he usually remained unshaken by opposing arguments. His two children—a son and daughter—grew up in Hexham, but their mother died some years ago. His daughter is married to a medical practitioner on Tyneside.—*The Evening Chronicle* (Newcastle-on-Tyne).

CORRESPONDENCE.**THE UNRESTRICTED SALE OF TUBERCULIN.**
Sir,

The leading article of *The Farmer and Stockbreeder* dated Aug. 11th, contains the following paragraph:

"Broadly, we are inclined more than ever to the belief that the Government should take steps to control the use of tuberculin. It should not be in the hands of the unskilled, and we use the term relatively as applied to professional men and laymen. It should not be open to any breeder to throw his suspects upon the market without declaration, otherwise the unsuspecting may be trapped. We do not believe in too much interference with the liberty of the subject, but there is such a thing as protecting the unwary and inviting confidence in the cattle business. No surer way to attain this ideal could be taken than by controlling the use of tuberculin so that the test might be used without being abused. Even with the margin of error commonly ascribed to its reactions, it is the only diagnostic that we have, in which respect it is of infinite value."

Also under "Current Notes" we read the following:

"The control of the tuberculin test is, we believe, urgently needed. We might then have a standardised serum and abolish the possibilities underlying the cleansing of herds to the detriment of those who buy in good faith cattle that have reacted."

The only argument of any weight raised against placing restrictions on the sale of tuberculin was that farmers and stockowners might object. Now that this

very widely read and influential agricultural paper has expressed such strong approval, this objection falls to the ground.

Three resolutions in favour have been passed by three very representative meetings of veterinary surgeons, and if these have been forwarded to the proper authorities and are supported by the profession we should look forward to results.

Another reform that is asked for by owners of pedigree stock is the standardisation of tuberculin, and no one will appreciate the need of this more than the veterinarian who has to decide whether an animal is tuberculous or not by means of the tuberculin test, and by that alone.—Yours truly,

Reading, Aug. 13.

G. P. MALE, M.R.C.V.S.

PROF. HARVEY CUSHING ON VETERINARY SCIENCE.

Sir,

In the address in surgery delivered before the Seventeenth International Congress of Medicine by Dr. Harvey Cushing, and reported in *The Lancet* of Aug. 9th, 1913, the following remarkable passage occurs:—

"Though less true of many European countries, where veterinary institutes which are doing admirable progressive work are under Government control in close association with universities, in the United States, and I think the same is true in a measure of Great Britain, most veterinarians have profited not at all by the advance in general medical knowledge of the past generation. This applies particularly to veterinary surgeons who still trust, in the operations which they venture to undertake, to the rough and casual methods of old, with scant if any pretence to the modern refinements of skilful anaesthetisation and aseptic surgical technique. Little wonder that people who are aware of this difference prefer to have their pets, when in need of surgical care, operated upon in an experimental laboratory rather than in many of the established veterinary hospitals. Some years ago, in the surgical laboratory at Johns Hopkins, this work grew to such proportions that a course covering the technique of operative procedure was offered to a group of veterinarians, who there for the first time learned methods which would enable them to save valuable animal lives by procedures which they had considered impossible, and which for the general run of veterinary surgeons had been impossible. [It was during this laboratory course that a woman prominent in the local anti-vivisection circle, who owned a number of cherished and interesting dogs, brought one of them, a valuable bull-terrier, to be operated upon for an extreme vaginal prolapse—one of the complications of whelping incidental to these highly bred pets. The owner was so gratified by the result that the animal and one of its mates were subsequently brought to the laboratory to have their ears pointed and tails docked—a request which of course was refused. Such are the inconsistencies of mankind]."

This is certainly not a compliment to the veterinary profession; fortunately it is not true, but perhaps it can be excused on the ground that the speaker had no knowledge of veterinary science.

This charitable view is reasonable if we refer to another part of the address in which it is stated that Copeman discovered the "bacterial cause of distemper and a successful method of inoculation against this most fatal and distressing canine disease."

The learned Professor cannot be acquainted with the progress of veterinary surgery in the British Isles, whatever he may have been told about the subject in America. I have no doubt that the veterinary press in America will challenge his statements and show up his inaccuracies and prejudiced views, because being Professor of Surgery in Harvard University, one would imagine that he would have made some enquiries before offering such a gratuitous insult to a profession which is represented in his own University.—Yours etc.,

Cork.

E. WALLIS HOARE, F.R.C.V.S.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1311.

AUGUST 23, 1913.

VOL. XXVI.

THE INTERNATIONAL VETERINARY CONGRESS.

We are reminded of the rapid approach of this Congress by the increasing frequency of references to it in Continental veterinary journals. The approximate date of the next meeting of the English Organising Committee, for instance, has just been published by more than one foreign journal. As a matter of fact, the actual meeting of the Congress is now practically a year distant; but the great bulk of its organisation will have to be completed many months in advance, and the most important part of the work will begin in earnest at the next meeting of the Organising Committee early in October. A good influx of new subscribers before that date will immeasurably lighten the responsibilities of the Committee; for we need not point out how greatly their work will be facilitated by a full exchequer. We hope that by next October the Treasurer will be able to announce that he has secured at least the minimum sum necessary for success; and as many of our members have not yet subscribed at all, that can easily be accomplished. One thing that is necessary is that interest in the Congress should increase here as it is increasing abroad.

THE TUBERCULOSIS ORDER.

Practitioners who are at all concerned with bovine tuberculosis, whether they are inspectors or not, will find the recently published discussion of this Order by the Veterinary Inspectors' Association interesting reading. Thanks largely, in all probability, to the line taken by the opener, the discussion was eminently practical and business like. It was a comparison of experience gained in three months working of the Order; its perusal teaches us a great deal of the use and limitations of the measure; and it abounds with suggestions both for the working of the present regulations and for their future extension. At present, the Inspectors' Association has more than justified its existence by holding such a meeting; and similar ones in future, as further experience of the Order is gained, will help to shape the lines of its inevitable modification and extension.

Meanwhile, the Board of Agriculture's returns of the work under the Order in July, which we published a fortnight ago, show how urgently the measure was needed. A few cases have occurred almost everywhere; though not many individual counties can show a large number. But so far it seems clear that, when the Order has been in force a year, it will have removed some thousands of the most infective cattle in the kingdom, and some local authorities have not yet begun to work it in earnest, and owners have not yet learned the need to report. But, in any case, it will be a good beginning.

EPIZOOTIC LYMPHANGITIS AND ITS TREATMENT.

In this article I shall only briefly describe the cause, nature and symptoms of the disease; for a detailed account I would refer the reader to the work by Pallin, where it is well described, my principal object being, to bring to the notice of the profession the results I have obtained in its treatment both preventive and curative.

The disease has been known in countries in the East such as India, China, Japan, for a considerable time, and it is prevalent also in other countries such as the Philippines, Mauritius, Northern Africa and parts of Europe. A few years ago it was introduced into the British Isles from this country, but was successfully dealt with by stamping out.

I think, however, that the conditions there are not so favourable to its spread and development as in other countries.

The disease is one affecting the lymphatic system of the skin and sub-cutis, producing usually well marked symptoms or lesions in the form of pustules (buds), sores or ulcers or both, along the course of lymphatic vessels, which in most cases are more or less thickened or "corded," due to the invasion of these parts of the organism by a "cryptococcus."

Any part of the integument may become affected, but certain parts are more liable, or perhaps more commonly affected, than others; these are the limbs, on the inner parts of the thigh and arm, the reason being, no doubt, that the legs are more liable to wounds from a variety of causes, such as kicks, pricks from thorns and other injuries.

Although the lesions are met with most often in the thigh or arm, I think that the infection has gained entrance lower down, below the knee or hock, and is carried along the lymphatic vessels, which in this situation are smaller and probably not so well supplied with glands, until it reaches a point higher up where it becomes arrested and there propagates. Except in one instance, I have not seen a definite cording of the lymphatics below the knee or hock although there may be one or two small buds or ulcers, the thickness of the skin here no doubt prevents the smaller vessels from showing up.

The thickened or corded condition of the lymphatic vessels and glands is an inflammatory one produced by the presence of the organism. The swollen gland is the pustule or bud which usually bursts and discharges a yellowish pus rich in organisms. In some cases the lesions are associated with a good deal of inflammatory swelling or œdema, to the thickness of an inch with the edges well defined, as in a case of purpura.

The infective nature of the disease is well known to those acquainted with it, but the infection spreads comparatively slowly, and is more or less localised except in a few instances where the disease appears to spread rapidly. A number of buds with intervening corded lymphatics may appear in such cases almost simultaneously, showing that the infection has passed rapidly through the vessels until it was arrested in a group of glands. I have seen cases where the owner stated that the lesions, which were well marked and fairly numerous, had appeared in 48 hours. In an outbreak among 120 transport mules which were inspected daily, lesions in some appeared in 24 hours (unbroken buds) and upon careful examination no wound could be detected by which the organism could have entered. In these cases the infection was not carried by harness, as the animals were in strict quarantine and not being worked.

The infection, if not checked, will spread until it affects almost the whole of the lymphatic system of the skin and underlying parts, and would in all probability produce death from exhaustion or "toxæmia," or both, if the disease were left to run its course. It is stated that the disease sometimes becomes generalized, with lesions in the internal organs, but personally, I have not met with it. From my experience the disease spreads more rapidly in the donkey than in other equines.

Once the infection has obtained a foothold in a stable or other premises it has been a difficult matter to destroy it. I think it probable that the organism is to be found almost anywhere in the soil in some localities under certain conditions, similar to the organism of tetanus; this point, however, requires further observation, and if correct will explain the origin of many cases where the source of infection is obscure. It is, of course, conceivable that localities where the disease has previously existed will be a fruitful source of infection.

The infection in this country (Natal) has confined itself principally to the coastal districts, probably the conditions there favour its growth, though it has occurred further inland as well as at much higher altitudes, but in these places the method in vogue of dealing with the disease—stamping out and quarantine was much more successful.

PREVENTION.

All possible precautions have been taken to prevent the spread of infection when a case occurred on a property, particularly if there were any in-contact animals, and in some places there are many such, as on some of the sugar estates where large numbers of equines, chiefly mules and donkeys are kept.

The procedure briefly is as follows; The infected animal is destroyed and the carcass suitably disposed of. All in-contact material is disinfected or destroyed, harness is immersed in a solution of disinfectant for 24 hours; shafts, poles, swingle-bars are repainted; trek chains are put into a fire for a time, and even the attendants hands are disinfected. The stable is properly treated or destroyed,

but with all these precautions the disease continues to spread.

It appeared to me that there must be some more potent factor conveying the disease, at least in the majority of cases, than any of the objects enumerated, as I have only seen a very few lesions which could be put down as having been directly caused through in-contact material. There is no doubt, however, that infected harness would convey infection should it come in contact with a wound.

I have seen many cases of infection of the brachial and prepectoral glands which at first sight appeared to have become infected from the collar or breast harness, but on examination these were in every case an extension of the disease from below.

I have come to the conclusion that the factor mainly responsible for the spread of infection is flies. It is well known how flies will discover a wound, however small, and as many species—among them the ordinary stable fly—are blood suckers, they make wounds themselves, and it only requires a drop of blood to attract more; the wound is thus enlarged, and suppuration invariably follows. This condition is frequently seen at the back of the knees, where the constant movement prevents or retards healing.

With the object of preventing the attack of flies to wounds, I use a mixture of Stockholm tar and oil. Tar is cheap, a good antiseptic, can be obtained at almost any house in the country, and I know of nothing better to keep away flies.

In areas under quarantine, this treatment of all wounds, no matter the size or how caused, is carried out as one of the conditions of the quarantine notice (Any condition thought desirable can be imposed under the Stock Diseases Act), and all owners of equines, where possible, more particularly those in the vicinity of the outbreak, are advised to use it.

With this preventive treatment the results have been very satisfactory. In twelve months the number of areas in quarantine have been reduced from forty to four. I may state that restrictions are imposed until at least six months have elapsed since the last case.

Previously in these areas an occasional case or more would appear at longer or shorter intervals, thus extending the quarantine. For example, one owner had been under restrictions for three years, and another nearly two years, with the loss of 33 and 27 animals (destroyed) respectively, the cases occurring at intervals of from two to eight weeks. No more cases have taken place at either of these places since the preventive measures have been carried out.

I mention these facts to show that if flies are kept away from wounds the chances of infection are at least brought to a minimum.

TREATMENT.

Epizootic lymphangitis is usually described as being a practically incurable disease, in that no method hitherto adopted has given satisfactory results, and that treatment should only be undertaken in selected cases and under special conditions.

Recoveries have, however, been brought about by treatment with various caustic agents, more or less violent, and surgically by the total extirpation of the affected parts—that is, the lymphatic vessels, glands and the skin covering them. This latter method, in fact both, if a violent caustic is used, are unsatisfactory, for the reason that the resulting wound is severe, takes a long time to heal, and is in constant danger to reinfection. Moreover, such treatment cannot be applied if the area involved is of any size or in the near vicinity of any important structures.

My object was to obtain a treatment that was effective and as simple as possible, and the results obtained, shown in the accompanying table, are, I think, most promising, and would indicate that the disease is not so resistant to treatment as it appeared. Although the number is not large, the results are those of the treatment of 15 consecutive cases.

The buds are opened, preferably with a cross incision, to well expose the interior, and the cavity thoroughly curretted to remove as much as possible of the infection with the instrument. All discharge and *débris* should be put into a strong solution of disinfectant which can afterwards be dis-

posed of. The exposed surface is then filled with crystals of Permanganate of potash, each bud being treated similarly. The ulcers as a rule have no cavity, and require only to be well scraped with the scalpel and the crystals applied. If the lymphatic vessels are much thickened, and this is sometimes irregular, they are opened at the thickest part and treated in a like manner, but unless they appear to contain pus it does not seem necessary to interfere with them, as they usually disappear. Some cases, however, require more frequent inspection than others, and any fresh buds that appear are treated as required.

It is not advisable to wait until the bud comes to a head before treating as this only delays matters. If a nodule is detected in the process of formation it should be cut down upon and treated or removed, as this lessens the amount of infection to be dealt with.

In those cases where the lesions are accompanied by an inflammatory œdema, a little Arsenic, Iodine, and Resin is given, as I think it helps to disperse the swelling, though in simple cases this is unnecessary.

There is sometimes a good deal of hæmorrhage from the part operated upon, but I have found the

DETAILS OF CASES OF LYMPHANGITIS TREATED.

Subject and Lesions.	Treated.	Remarks.
1. Donkey stallion. Buds and ulcers on prepuce, abdomen and inside thighs.	1912. Sept. 11	A simple case.
2. Four cases among a span of donkeys. Lesions on both fore and hind legs (thighs and arms), also on abdomen and chest.	Oct. 10	Two of those cases were somewhat severe with much thickened lymphatics.
3. Horse. Numerous lesions (advanced) covering the whole of one fore arm and extending through the axilla into the brachial and pre-scapular glands, which was the size of a cocoanut.	Nov. 30	* A severe case which in four days was rapidly spreading in the other limb.
4. Horse. Lesions on side of chest and abdomen associated with much inflammatory swelling.	1913. Jan. 18.	Severe case, swelling extending from brisket to near sheath. Treated a second time. Lesions all healed, but subject died of horse sickness.
5. Horse. Lesions extending from the near eye over the masseter muscle into the submaxillary space involving the gland, thence down the jugular furrow to near the shoulder. Cording of the lymphatic vessels was well marked down the furrow.	Jan. 18.	Not severe, except the masseter muscle, where the lesions were diffuse.
6. Horse. Buds and ulcers with corded lymphatics and associated with inflammatory swelling on the near ribs.	April 18	A severe case: treated twice.
7. Mule. One lesion, an ulcer on near side.	May 9.	Simple case. Subject died later of horse sickness.
8. Mule. Buds and ulcers on chest and ribs extending down one fore leg and posteriorly over the abdomen to near the mammary gland.	„	A severe case, with much lymphatic swelling, wounds all healed, but subject later died of horse sickness.
9. Horse. Unbroken buds on both fore arms extending through the axillæ and over the shoulder joints, with a few lesions on the ribs of one side.	„	A severe case, 25 places treated.
10. Donkey. Buds and ulcers inside one thigh.	May 29.	A simple case.
11. Donkey. Lesions inside one arm and thigh with corded lymphatics.	„	Not severe, but secondary lesions were treated again on June 16.
12. Donkey. Buds and ulcers with corded lymphatics extending from the hock to the groin, also inside one arm through the axilla and over the shoulder joint.	June 16.	A severe case associated with much cording of the lymphatic vessels.

Total treated, 15. Cured, 14: Destroyed, 1.

* Destroyed.

Permanganate to act as an excellent styptic. The parts around the wounds are then dressed with the tar and oil, in the proportion of one of tar to four or five of oil. Castor oil is best, as it adheres better and thus only requires renewing every two or three days. If used in stronger proportions the tar will excoriate the skin and remove the hair. The subject is isolated and later treatment that may be necessary is carried out as before, though in most cases nothing more is required, and the wounds heal in from two to three weeks.

It is hardly necessary to add that if a number of places have to be treated, the subject should be cast and well secured. There does not appear to be any recurrence of infection after the wounds have all properly healed, as the first case treated by the writer was twelve months ago, and to-day the animal is healthy and regularly working.

The permanganate stains the hands a good deal, but this can be removed with pumice stone or a solution of oxalic acid. An interesting feature is the amount of heat generated by the oxidation of the salt; I have not had an opportunity of recording the amount, but it is uncomfortably hot to the fingers.

In all the cases shown in the table the disease was verified by microscopical examination. The method of staining the smears was the process used by Mr. Goulé, Government Veterinary Surgeon, Natal, which is rapid and gives excellent results. It is applied as follows: A few drops of a saturated alcoholic solution of Gentian violet are placed upon the smear with an equal quantity of water. Staining is complete in three minutes, wash, dry, and examine as usual.

A. F. HARBER,
Government Veterinary Surgeon

Durban, Natal.

TWO CASES OF PENTASTOMUM TÆNIODES.

The supposed comparative rarity of the occurrence of this parasite in the nasal chambers of dogs in Great Britain, has induced me to record these two cases that have come under my notice. I think that it may be found that it is not so rare in this country as some authorities would have us believe,

Hutyra and Marek in Vol. ii. (p. 25) state "the adult parasite is found preferably among the dogs of butchers, shepherds and hunters; it is found very rarely among other dogs, *not at all among pet house dogs*."

The first case, which came under my notice some few years ago, was in a bulldog of my own. The usual symptoms of sneezing, etc. were observed, and on examining the nostrils, a body was seen, which at first sight looked like a cotton thread. On being withdrawn it proved to be an excellent specimen of this parasite. A smear of the nasal discharge on microscopic examination, showed the ova of this parasite in large numbers. The treatment advocated by "authorities" of injecting into the nose by means of a syringe various solutions

such as boracic acid and vapours of chloroform, etc., proved to be quite useless. At length, a solution of common salt in water (one teaspoonful of salt to 3-4 tablespoonfuls of water) was injected up the nostrils, the dog's head being held up during the procedure. The result was a complete cure.

The second case occurred only last week, and is of interest on account of the fact, that the authorities just quoted, stated that it does not occur at all among pet house dogs. A client brought a specimen of this parasite which he had taken from the nose of his toy Yorkshire terrier, and he stated that this was the second one that he had removed. The treatment that proved successful in the first case has been advised.

It was only in the July 26 number of this paper that Mr. Tudor Hughes recorded a case of this parasite as occurring in the nasal cavity of an otter hound, and as he gave briefly the life history of the parasite then, I do not propose to add any remarks with regard to this.

J. F. D. TUTT, Class D.

R. V. C., London.

NORTH OF IRELAND VETERINARY MEDICAL ASSOCIATION.

A general meeting was held at 7, North Street, Belfast, on Thursday, the 26th June, when the chair was occupied by the President, Mr. J. A. Jordan, M.R.C.V.S., City Veterinarian, Belfast. Others present were Messrs. John Loughran, J.P., Aughnacloy; W. C. M. Smith, Newry; John Kernohan, J.P., Ballymena; A. M. Crichton, Lisburn; J. A. Gault, Ballymoney; Howard M'Connell, Armagh; John M'Lean, J. Ewing Johnston, and F. W. Emery, Belfast.

On the motion of Mr. Loughran, seconded by Mr. Smith, the minutes of the last meeting were taken as read.

Apologies for inability to attend were received from Capt. Hodgkins, Alexr. Monro, James Gregg, John McAleer, John A. Thompson, J.P., and J. J. Ross.

THE NEW TUBERCULOSIS ORDER.

Opening by HOWARD M'CONNELL, M.R.C.V.S., Armagh,

Mr. M'CONNELL, who was very heartily received opened his remarks by saying that the new Order was most comprehensive and far-reaching, and one through which the members of the veterinary profession were afforded a great opportunity of manifesting their usefulness to the community. The Department of Agriculture had arranged for veterinary surgeons, who held inspectorships, to attend Dublin, where they were received by the Chief Inspector of the Veterinary Branch—D. S. Prentice, Esq.—who gave a very clear and able exposition of the Order, and answered any questions put to him by those present. The Order is of a compulsory character, and deals with two forms of tuberculosis only, viz., (1) tuberculosis of the udder, and (2) tuberculosis with emaciation; all other forms of the disease being excluded from its scope.

Any person having an animal coming under either of these classifications must report the fact to the police of the district wherein the animal is, the police transmitting all such information to the local authority who, in their turn, must inform the Department and also the sanitary authority, if they are not themselves acting as such.

The owner of an affected or suspected animal must forthwith have it isolated, and if it be a milch cow the milk must not be mixed with that from other cows or used for any purpose until it has been thoroughly sterilised, and all utensils used must be effectively cleansed with boiling water before being again used for milk.

It will be observed that it now becomes obligatory on a veterinary surgeon to report any instance of an animal, coming within the scope of the Order, that may come under his observation, and for each such report he must be paid the sum of two shillings and sixpence. It will be well to remember that the V.S. is not called upon to report to the police but direct to the local authority, who, upon the receipt of such report, must act as if the information had been conveyed to them by the police.

The next procedure is for the local authority to arrange for such veterinary examination as may be necessary to ascertain whether or not any cow upon the premises from which the report has been received is suffering from tuberculosis of the udder, or whether or not any bovine animal thereon is suffering from tuberculosis with emaciation. For this purpose the veterinary inspector may use the tuberculin test if he receives the consent in writing of the owner, but not otherwise.

For the purpose of examination an inspector may take samples of milk, faeces, urine, or any abnormal discharge from any bovine animal on the premises where the disease is reported from.

Having completed his examination, the veterinary inspector must furnish his report to the local authority and to the Department, and the local authority, if not themselves the sanitary authority, shall send a copy of the report to that authority.

Now, if the inspector's report confirms the existence of the disease as coming under the classification already referred to, arrangements have to be made for slaughter; but if the owner gives notice in writing that he objects to this course, further action must be delayed until the sanction of the Department is obtained, and no special authority will be given if the animal in question is valued at over £30 if, and so long as, the animal is detained and isolated and the milk, if any, dealt with in accordance with the regulations.

Special provision is made to avoid interference with the powers possessed by the sanitary authority under Section 18 of the Tuberculosis Prevention (Ireland) Act, 1908. The valuation of animals intended for slaughter appears to be a complicated procedure. The valuation can be agreed upon between the local authority and the owner of the animal, the value to be estimated on the general condition it presents at the time. But should they fail to agree, a valuer must be appointed by the local authority, or, on their application, by the Department.

In ascertaining the value of an animal due regard must be given to any Act, Order, or regulation dealing with the sale or use of milk, milk products, or carcasses for human food.

Two valuations have to be made, one on the basis that the animals will be found tuberculous, and the other on the basis that evidence of the existence of the disease will not be revealed. It will therefore be seen that a post-mortem examination becomes a necessity, and it should be of the most careful and searching character, as the amount of compensation payable to the owner will be regulated by the certificate given as a result of the autopsy. Should the local authority fail to carry out the examination, or if the certificate of such examination does not show that the animal was suffering from tuberculosis, compensation equal to the value of the animal as agreed upon, with the addition of one pound, must be paid. If, however, the certificate of the examination shows that the animal was suffering from tuberculosis (not being advanced tuber-

culosis) three-fourths of the value of the animal, as agreed upon, or certified for, shall be paid, but certain amounts are to be deducted, such as one-half the cost of any valuer appointed, or of any veterinary surgeon employed if other than the veterinary inspector. If the certificate of the examination shows that the animal was suffering from advanced tuberculosis, then the compensation payable will be one-fourth the value agreed upon, or certified for, or the sum of 30s., whichever sum is the greater, but half the cost of valuation and examination can, under certain circumstances, be deducted by the local authority.

The Order clearly defines the conditions which, if found on post-mortem examination, shall constitute advanced tuberculosis.

There are other provisions dealing with cases detected in fairs, markets, railways, inspection yards, isolation, disinfection, etc., but they are definite and appear to present no difficulties.

In conclusion, Mr. M'Connell instanced a few cases that had been reported to him; the first was a valuable bull that had reacted to the tuberculin test, but could not by any stretch of the imagination be looked upon as a case of tuberculosis with emaciation; his only duty therefore was to explain to the owner that it was not a case coming within the regulations; the second case was that of a cow suffering from a cancerous condition of the mammary gland, and the next, a cow with a normal udder but with a somewhat elevated temperature. He trusted that the members of the profession would do their best to carry out the duties efficiently and without any undue regard to their own pecuniary advantage.

Mr. CRIGHTON said the Order was one of the most important and far-reaching that had been promulgated for some time, and he foresaw a great amount of difficult and trying work for those entrusted with the discharge of the various duties it imposed. He did not think they should undertake the work in any philanthropic spirit; the duties were important and directed towards the benefit of the community, and he therefore thought, that as the labourer was worthy of his hire, we, as a profession, need not hesitate to see that we were adequately remunerated for the time and trouble taken up in connection with this all-important duty.

The discussion was very ably continued by Messrs. Loughran, Gault, Kernohan, Smith, M'Lean, Johnson, and the President, who specially thanked Mr. M'Connell for his very valuable contribution to the subject.

PRESIDENTIAL ADDRESS.

Mr. J. A. JORDAN, M.R.C.V.S., Belfast.

Gentlemen,—In the first place, allow me to express my deep and heartfelt gratitude for the honour you have done me in electing me your President for the year. I can assure you the honour was unexpected, and I feel certain that you might have made a much better selection. However, I shall do my best, and I hope I may be able to carry out the duties of the office as well as my predecessors have done. The success of an Association such as this largely depends on the interest taken in it by the members. I would therefore appeal to you to attend all our meetings and enter whole-heartedly into our discussions. When the time comes for me to vacate the chair I trust that the Association will be nothing the worse, and that you will have no cause to regret the confidence you have placed in me.

I am pleased to know that I will have the assistance of such an able Secretary. To my mind there is no office in any Association which carries greater responsibility than the Secretary. It is not as a rule a much sought after position; indeed, it is often a very difficult matter to secure a proper person able and willing to take the position. I wish therefore to offer you my congratu-

lations on your choice. In Mr. Emery you have a man endowed with gifts of a very superior order, which I feel assured he will use for the furtherance of this Association's interest and for the unholding of the dignity of the profession. We are bound to prosper under his secretarial ability. He will no doubt need your assistance, for I am, from my own personal experience, quite aware of the many difficulties in which secretaries are frequently placed. Papers are difficult to secure and it is always up to your Secretary to furnish you with something for discussion, therefore every member should endeavour to bring forward something of practical interest for discussion.

Before offering you a few remarks on matters of everyday interest, I would wish for a few moments to refer to the much lamented death of a member of this Association, one we could ill afford to lose. I refer to the late Mr. Matthew Hedley. By his decease the profession in Ireland is very much the poorer. His loss will be keenly felt, especially by all those who had the pleasure of coming in contact with him whether in private or in the performance of public duties. He was broadminded, far-seeing, generous, thoughtful, and above all a worker. He gave ungrudgingly of his services in the interest of his profession. The recent outbreak of foot-and-mouth disease greatly added to his work, and his life was undoubtedly shortened by his untiring devotion to duty. His memory will long linger with his colleagues and with none more so than myself. I have lost in him a friend who was every ready to help me with his counsel and advice. His works both inside and outside the profession will remain as a memorial to him.

I would also wish to refer to an immensely popular and pleasing feature of the year, viz., the conferring of a knighthood on Mr. Stewart Stockman, Chief Veterinary Officer to the Board of Agriculture and Fisheries. I am sure we are all pleased at such an honour being conferred on a member of our profession, and wish Sir Stewart many happy years to enjoy his distinguished honour.

Very little of moment has happened in matters politic during the past year.

The amalgamation of Veterinary Societies—after a very chequered career—is, I am pleased to say, an accomplished fact. Dr. Bradley and Prof. Gofton are to be admired for the plucky manner in which they undertook this task, and they are to be congratulated on the success which has crowned their efforts. In the reconstructed "National" I feel we have a machine which, if carefully manipulated and kept running smoothly, should do an immense amount of very useful work to advance the interests of our profession. Much good can be accomplished by combined action. If we wish to succeed we must unite and agitate.

The Veterinary Surgeons Act Amendment Bill still awaits Parliamentary sanction. Let us hope that when that is granted we will hear no more about the financial difficulties of our College. It is to be regretted that the passage of this Bill through Parliament has been so protracted, for no doubt money is urgently required.

I am pleased to learn that a Special Committee of Council has been appointed to consider a scheme whereby the Fellowship Examination might be revised. This to my mind is a decided step in the right direction. If the Fellowship Examination was split up into different branches it would then be possible for men to gain their "Fellowship" in their own special branch of work. A considerable number of our members are engaged in Public Health and Departmental duties. These men should surely have an opportunity of gaining their "Fellowship" in their own particular branch.

As you are all aware, the vexed question of the control of tuberculosis has been exercising the minds of our legislators for a considerable time past. They have

at last decided that the disease should be scheduled and brought under the operations of the Diseases of Animals Act. Accordingly, the Department of Agriculture and Technical Instruction for Ireland has now issued their Tuberculosis Order, 1913. This Order I consider to be the most important one that the members of this profession have had to deal with for some considerable time. It has given the profession the opportunity of demonstrating to the general public that they, and they only, are the proper persons to have control of the diseases of animals. A great deal of course depends on the manner in which the provisions of this Order are carried out by those who are entrusted with the work. Their actions will be watched very closely by certain members of the sister profession, who will not be slow to grasp any opportunity whereby the work of final diagnosis may be passed over to them. Very little time has been given to make the necessary arrangements for carrying out such an important and far-reaching Order, but I have every confidence that the members of the profession will rise to the occasion and give a good account of themselves.

The year 1914 should be a memorable one to the members of the profession in these Islands, for it is then that the International Veterinary Congress will hold their annual meeting in London. This should be taken by every member of the profession as a compliment. Those responsible are naturally anxious that they should know as soon as possible what amount of money they are likely to get. I understand that something like £3000 will be required to run this important undertaking and to entertain our guests in anything approaching the style the delegates from these Islands have been treated, when attending similar functions in other parts of the world. I feel sure it is the wish of every Irish veterinary surgeon, whether he hails from the north, south, east, or west, to reciprocate that hospitality in a manner befitting what it pleases strangers to call us—"the most hospitable people in the world."

As an Association we have already subscribed to the funds, but I wish to-night to appeal to each individual member to try and give a something, no matter how little, to help to swell the funds. It is not necessary that you should give your subscription just right away. All that is wanted at present is your name and the amount you intend to subscribe. I shall certainly do what I can, and I have no fear a single member of this Association will be behind.

Just while I am in this strain I would wish to say a word or two regarding the Victoria Veterinary Benevolent Fund. I understand that funds are urgently required in order to carry on the good work of relieving distress, and I would therefore appeal to one and all to give as liberally to this most deserving fund as possible. The objects of this Fund are to assist those members of our profession who—more often than not from circumstances over which they have no control—have fallen upon evil days. It is also assists the widows and orphans of our deceased brethren in so far as its funds allow. None of us know what is in store for us or ours. Perhaps it is just as well. Let us therefore do unto others as we would wish that they should unto us. It certainly is a charity that should be supported.

I hope to be excused to-night for not referring at any length to the recent outbreak of disease amongst cattle in this county, which, as you are all aware, caused great financial loss. Some experts had no hesitation in pronouncing it foot-and-mouth disease; others of a very high scientific standard were not quite so bold, and contented themselves by calling it pseudo foot-and-mouth disease, whilst others, still more careful, only got the length of calling it "dirty mouth." Now, gentlemen, no matter what it was, it has gone, and gone as rapidly and as mysteriously as it appeared. I am sure we are all delighted, and now that it is gone the sooner

we get the dirty taste out of our mouths the better. I do not think there is anything to be gained in dwelling on the subject.

Allow me to thank you for your attention, and to express once more my appreciation of your kindness in electing me as President. I sincerely trust that the success which has followed this important Association may continue, and that our deliberations may serve to advance the interests of the profession to which we are all proud to belong.

Mr. EMERY proposed a very hearty vote of thanks to the President for his able and interesting address, and in doing so remarked that custom necessitated the passing of Presidential addresses without offering criticism, otherwise there were points dealt with by Mr. Jordan about which he might have had something to say. However, whether or not he agreed with certain questions that had been raised, he fully acknowledged the address was an able and interesting one; he offered his sincere congratulations.

Mr. LOUGHRAN, in seconding, thanked Mr. Jordan for his most interesting and instructive address. Carried by acclamation.

At this stage Mr. J. Ewing Johnson stated that he had been informed that, through the kind offices of our President, the Markets Committee of the Belfast Corporation had expressed their willingness to allow future meetings of this Association to be held at the premises of the new City Abattoir, and it was for the members to say whether or not they would accept the generous offer of this very attractive accommodation.

Mr. M'CONNELL, in proposing the acceptance of the very generous offer, said he thought such a desirable meeting place would render our meetings much more attractive in future, and act as a great incentive to a better attendance, and he had great pleasure in moving that a most hearty vote of thanks be passed to the Committee for their kindness. This was seconded by Mr. J. E. Johnson, and passed by acclamation.

The following very interesting case was then brought forward by Mr. A. M. Crighton, M.R.C.V.S., Lisburn.

PYOGENIC FEVER ASSOCIATED WITH MULTIPLE ABSCESES.

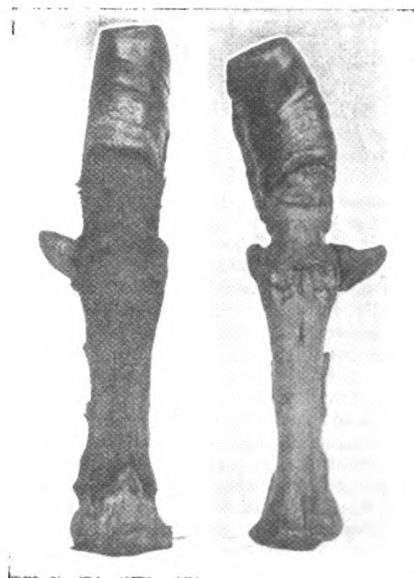

On the 28th May last I was called to attend a very valuable thoroughbred foal, aged one month. After enquiry and a very careful examination, I concluded that my patient was suffering from pyogenic fever. Abscesses had formed above and below the left eye, the usual febrile conditions obtained, and diarrhoea prevailed. I gave the necessary instructions for careful nursing, and prescribed small doses of Pulv. rhei et mag. carb. levis to be given three times daily in a little of the mother's milk. The abscesses, having matured, were lanced and the contents evacuated, the cavities were then syringed out twice daily with a suitable antiseptic solution. On my next visit I found other abscesses ready for opening. Diarrhoea still marked. I turned my attention to the dam and ordered a complete change of dietary, this was done on five or six occasions. I also treated her medicinally, prescribing, from time to time, Pot. chlor., Mag. sulph., Soda sulph., Soda hyposulphate, etc., but little improvement resulted. Turning to the foal, I tried Tenalbin in small doses three times daily. I saw a little improvement under this treatment. At each visit I found additional abscesses ready for opening, while there was evidence of others forming. The foal continued to drink, and, all things considered, remained in fair condition.

With the good weather, and under apparent favourable conditions, I ordered mare and foal to be put out to grass, and to my delight matters began to improve; the diarrhoea gradually subsided, and the foal soon presented a more healthy appearance, but on Saturday last I

opened the fourteenth abscess: this was situated right in front of the sternum, and the contents were of a similar character to that discharged from others. The abscesses were situated over the head on both sides, submaxillary glands, parotid glands, down the neck, even the upper and lower eyelids were affected. I shall be glad to have the opinion of members who have dealt with similar cases. Has any member tried "Streptocine" for this affection?

Mr. SMITH said he had had somewhat similar cases in which he adopted the usual treatment and careful nursing, with very satisfactory results.

Mr. JOHNSON considered this a case in which serum-therapy treatment was clearly indicated.

ABNORMAL PHALANGES IN A COW.

The President exhibited several excellent photographs of abnormalities and pathological conditions which had come under his observation from time to time. One photo presented the two forelegs of a cow, terminating in single digits. This was considered

unique, and in explanation Mr. Jordan said, it will be seen that in general conformation and appearance the feet closely resemble those of the horse, and in order to show that it is not only the horny hooves that are single, I have had a hoof removed, thus exhibiting the pedis, corona, and suffraginis, all of which are single with single articulations.

The subject was an aged cow in good condition, and was purchased in the Dublin cattle markets by a Belfast butcher and brought for slaughter in the usual way to the public slaughterhouse here.

The usual complimentary votes brought a very interesting meeting to a close.

F. W. EMERY, for Hon. Sec.

EASTERN COUNTIES VETERINARY MEDICAL SOCIETY.

STERILITY IN THE MARE.*

By A. F. CASTLE, M.R.C.V.S., Ipswich.

[ABSTRACT].

The immense importance of this subject has long been realised by the veterinary profession and others interested in the breeding of horses, especially thoroughbred stock. According to the General Stud Book, about 42 per cent. of English thoroughbred mares fail to produce foals annually, in spite of having every possible attention. This necessarily entails a great loss to the breeder, for when one considers that a large number of thoroughbred horses of fashionable blood are standing at fees from one to two hundred guineas, and, in exceptional cases, three, and even five hundred guineas, some idea may be formed as to the resulting loss to the owner, and in addition to the service fees there are the usual expenses incidental to the upkeep of the stud.

Sterility may be occasioned through structural or functional derangement or defect of the generative organs, and may be either temporary or permanent.

Age for Breeding. Very often two-year-old fillies are sent to the stud if they have been a disappointment whilst in training, or have badly "broken down," and possess exceptional blood lines. But fillies of this age are far too young for breeding purposes. It is often the procedure of breeders to put a filly that is slack in the loin to a horse, with the idea of causing a dropping of the flank and thus rendering this deficiency less noticeable; this applies more to the heavy breeds.

In breeding thoroughbreds, the third foal produced is often the best, and it has been found that the classical races are most often won by the third foal. When the mare has attained the age of five years she is generally considered at her best for breeding purposes.

When one wishes to determine the cause of sterility in any individual mare, one primarily notices the general condition of the mare, and then proceeds to examine the generative organs. For the thorough examination a vaginal speculum is necessary, and the most convenient pattern is that devised by Polansky. Before conducting such an examination, it is of great assistance if one can obtain information whether the mare has had a foal, or how many seasons she has been at the stud. If the mare has bred a foal, it is advisable to know when the foal was born, whether the mare is regular in coming in season, whether she was injured last foaling, and if she carried the foal the full period of gestation or not.

One then proceeds to examine. The perineum may be torn or ruptured, and thus the faeces may be passed through the lips of the vulva instead of normally per anum. In some cases the roof of the vagina has been

so badly lacerated during parturition that the rectum is directly connected with the vagina. One also notices any evidence of a discharge; it may be limited to a small collection of mucus, hanging from the vulva or dried around the lips. The whole of the skin on the inside of the thighs down to the caps of the hocks may be denuded of hair as a result of the irritation produced by the dribbling of an acid discharge. The hair in the tail or the undersurface of the dock may furnish evidence of a recent discharge.

Use of the Speculum. It is always advisable to procure the best light; if the sun is shining, one may arrange the mare so that the sun strikes directly into the vagina. If it is too dull to examine the interior with the unaided eye, one may use an electric torch. The os uteri is normally contracted, except at parturition or at time of oestrus, when it may be slightly relaxed. Relaxation of the cervix can be brought about by applying belladonna, or any similar sedative, to the whole of the cervix, or one can use hot water.

In examining the vagina and uterus one notices the following: The colour of the mucous membrane—the normal colour is a pinkish shade—which in diseased condition may be yellow, slaty blue, or greyish in colour. The presence of any discharge adhering to the walls or lying on the floor of the vagina or uterus. The condition of the os uteri, whether relaxed, firmly contracted, ulcerated, congested, inflamed, or presenting any other abnormality as flexion, laceration, or occlusion, etc. The presence of tumours, polypi, or abscess formation in the vagina or womb; false membranes closing the os, or hanging from any surface of the vagina or womb; any indication of laceration.

The term "split mare" is applied to those mares possessing a badly lacerated os, usually the result of a serious foaling, in which forcible extraction has been employed, or unskilful interference permitted—the laceration may vary in degree from a slightly torn edge to a tear on either side of the os, extending laterally for some inches, rendering the os chronically patent.

The causes of sterility may primarily be divided into Temporary and Permanent conditions.

Temporary. Those functional and structural diseases that are amenable to treatment, or which can be overcome by surgical interference, as in acute congestion or hyperæmia of the os, acute and subacute inflammation of the uterus; occlusion of the os uteri with false membranes, or tumours or polypi that can be surgically removed; catarrhal and inflammatory conditions of uterus and vagina that are curable; nymphomania (some forms); diminished sexual impulse; occlusion or spasm of os uteri; deviation or misplacement of os; chronic endometritis, as complication to parturition or epizootic abortion.

Permanent. 1. Chronic inflammatory condition of the ovaries, vagina, or uterus.

2. Some diseases of peritoneum associated with the formation of growths, thus rendering the escape of ova from fallopian tube impossible.

3. Absence of ovaries, formation of growths in substance of ovary, cystic ovary, nymphomania, chronic inflammatory conditions.

4. Lacerated os uteri, causing non-retention.

5. Inoperable tumours in wall of uterus or vagina.

DISEASES OF OVARY AND FALLOPIAN TUBES.

All the diseased conditions of the ovary and fallopian tubes are purely surgical, no medicinal treatment is of any avail. The great majority of these conditions are undiagnosable during life.

The ovaries are rarely removed unless the mare is a nymphomaniac, or the presence of cysts has been demonstrated by rectal examination. Cysts in this organ

* Read at the meeting at Ipswich on July 24 (p. 93).

are so large at times that they are readily broken by pressure per rectum.

Nymphomaniac mares are constantly in season, and are often confirmed kickers. But this condition more often calls for attention in harness mares than any others. When diseased conditions of the ovaries or fallopian tubes are diagnosed in the brood mare, she is usually at once discarded for breeding purposes.

The diagnosis is seldom satisfactory, and can usually only be formed after eliminating all other diseased conditions that can account for the sterility. But when a mare has been at stud for three or four years, and has been mated with a liable foal-getter, and the mare is constantly in œstrum, and no demonstrable cause can be found, it is usually safely assumed that the ovary or its tube are affected, and the mare is removed from the stud. Nymphomania is often caused by chronic metritis, or the presence of growths in the uterus or vagina.

DISEASES OF THE UTERUS.

Tumours or Polypi. The presence of a tumour or polypus is often discernable on introduction of the vaginal speculum. In some cases the only symptoms are a thick, tenacious discharge from the vulva, and the constant manifestation of œstrum.

The extent and situation of the growth can in some cases be determined on rectal exploration.

If the growth possesses a constricted neck or pedicle, it may be possible to effect its removal either by ligature or écraseur, but if the base is diffuse, it may be unwise to attempt removal; in the latter case the mare is useless for breeding purposes. Should total extirpation be practised it is advisable to well douche the interior of the uterus in order to remove blood clots or other accumulation that may have collected during the operation, but if there is any tendency to hæmorrhage it is advisable to delay irrigation.

Metritis. Catarrh or inflammation of the uterus is a frequent cause of sterility in the mare. It is often a sequel to acute inflammation arising from injury during difficult parturition. It often arises from prolonged retention of a portion of the foetal membranes, also as a sequel to the return of the uterus after eversion. It is a common sequel to sporadic and contagious abortion. Leucorrhœa is a chronic form of inflammation of the uterus. But there are a large number of cases of chronic metritis that are not readily accounted for which may be the result of low nutritive processes in the uterus.

The character and quantity of the discharge is subject to great variation. It may be thick, tenacious, muco-purulent, or it may be thin and watery, containing suspended particles of pus and mucus.

The quantity of inflammatory fluid varies in different forms of the disease, but in all cases this must be removed by a syphon or a syringe. A Reed's pump is very useful in these cases.

Treatment. In some chronic forms, a course of tonic medicine, including Nux vomica, Ferri sulph., Aloes, Gentian, etc., conjoined with good feeding and daily irrigation of the uterus with an antiseptic and astringent solution may be the only treatment required. In all chronic inflammatory conditions of the uterus and vagina a run at grass is always beneficial.

The selection of the disinfectant must be varied to suit the individual cases. I have secured the best results with the following—Aniodol, Chinisol, Protargol, Sodium bicarb., Lysol, Pot. permanganate, Ac. carbolic, Ac. boric, Zinci sulph. Practically all the disinfectants and mild astringents have been used for uterine irrigation. Where the quantity of discharge is very abundant, a weak solution of Sulphate of zinc with Alum or Plumbi acet. usually gives good results. Aniodol is one of the best uterine disinfectants. Chinisol must be used very dilute, for if in too strong a

solution, symptoms of straining and uneasiness are manifested.

In all these cases I have found a vulcanite tube about eighteen inches in length, attached to a pump or syringe to be the most suitable. The tube is perforated throughout its length, so that with a forcible supply of water the whole lining membrane is sprayed.

Leucorrhœa. This is one of the chronic inflammations of the glands of the uterus, and often of the vagina. The discharge is usually thin and milky-looking, or thick and presenting a starchy appearance. Usually odourless; it may be purulent, muco-purulent, or brown-coloured; it is very often intermittent. The only external evidence of the disease may be the collection of a small quantity of discharge, adherent to the lips of the vulva or collected at the lower commissure. The mare may not, but usually does, suffer constitutionally as a result of this disease. It is most commonly found affecting aged mares, and those that have been barren for some years. In some cases the inflammatory condition appears to be limited to the cervix and vagina, and is usually seen after the inflammation of the uterus has subsided. When the uterus and vagina are affected, the whole of the organs appear to be in a relaxed state, and the os uteri may be dilated. The lining mucous membrane of the uterus and vagina may be greyish or yellowish in appearance.

On introduction of the speculum, the condition is usually readily diagnosed, the "ballooned" condition of the vagina with the relaxed os immediately attracts one's attention, and the accumulation of whitish, thick discharge is usually present.

Treatment. This must be very energetic, and even then the trouble tends to be very obstinate. Many old standing cases appear to defy treatment and relapses constantly occur. Warm injections of Zinc sulphate and Alum or Tannic acid once or twice daily may be persisted with for a time, and then varied with cold injections. Solutions of the following may be tried:—Silver nitrate, Ac. carbolic, Izal, Aniodol, Salicylic acid, Condy's Fluid. Internally, tonics may be administered. Good feeding should be advised.

Dropsy of Uterus. When this condition is present, it is inadvisable to undertake treatment; the trouble is usually far advanced in these cases, and other organs are often badly affected.

Malformation of the Vagina. The vagina is occasionally found to be malformed, and in some instances the passage has only been six or seven inches in length, and in some instances injury to the mare at coitus has resulted. The length of the vagina varies greatly. In some animals when the vaginal speculum is introduced it is only with difficulty that one can reach the os uteri, whilst in others it is impossible to insert the speculum properly on account of the shortness of the passage.

In all mares at the time of œstrum, the os uteri appears to have been forced more posteriorly than at other times, and consequently the length of the vestibule of the vagina appears to be shortened.

In those mares possessing an abnormally short vagina it is advisable to produce artificial insemination rather than risk injury to both horse and mare. In some cases the mare will appear to sit down on the stallion at the time of coition, and as a result there is often injury to the penis and bruising or laceration of the anterior portion of the vagina.

Inflammation of the Vagina. The inflammatory process may be a result of extension of inflammation from the uterus. It is often seen as a result of bruising or laceration received at the time of parturition. There is also a specific or contagious vaginitis recognised, but inflammation is very often encountered when it is impossible to ascribe it to either of the above mentioned, more especially in aged and barren mares. In chronic

forms of leucorrhœa that have been months in existence, it is not unusual to find the inflammation restricted to the vagina, the inflammatory process having subsided in the uterus. In the chronic forms that are usually encountered in sterile mares, the affected areas may be small or large. In some cases it is diffuse, whilst in others only isolated localised lesions are discernable. One often discovers patches of congestion, inflammation, ulceration and ecchymosis on examination with the speculum. The anterior portion of the vestibule appears to be especially subject to this localised form.

The colour of the mucosa may vary from a slightly deeper pink than normal to dull grey or yellow. The yellowish and greyish tints are most commonly associated with relaxation of the walls of the vagina, and appear to be due to a general lack of tone.

The discharge may be present in small quantities, only appreciable with the speculum, or it may be seen escaping from the vulva after micturition or when the mare is laying down. In many cases the exudate is in the form of a thick milky scum, or it may even be stiffer in consistency, adhering to the lateral walls at the anterior portion of the tube. When removed it comes away in flakes, leaving the denuded surface in a state of congestion, with a great tendency to bleed. Most of these cases are associated with ulceration. Sometimes the discharge is frothy, whilst in others collections of mucus on the walls are readily discernable. In the chronic form of leucorrhœa, restricted to the vagina, the character of the discharge is similar to that found in the uterus under the same condition. It may be milky or starchy in appearance.

In vaginitis the discharge may vary from a collection of serous looking fluid to that containing pus, suspended particles of exudate, and lining epithelium. Large films of greyish material may escape or be floating in the limpid serous fluid.

In some cases a bluish-grey film appears to be superposed to the mucous membrane with localised patches of ecchymosis. This is usually found in old standing cases and is associated with a relaxed condition of the vagina. In many cases the faulty secretions are very acid in reaction, this is absolutely fatal to the existence of spermatozoa.

Treatment. In all cases it is of primary importance to first thoroughly cleanse the organ; this may be accomplished through the agency of soap and hot water. One can either use a sponge, tow, cotton wool soaked in water, or inject the solution. Personally, I prefer to fasten a quantity of tow round or in one extremity of a suitable stick. I think tow is preferable to a sponge, for once used it may be thrown away, but sponges are rarely cleaned satisfactorily. This is a special instrument made for carrying a sponge, tow, or cotton-wool.

Any discharge that may have collected on the inside of the thighs, about the perineum or the hocks, should be removed, and the application of an emollient may be advisable to prevent further excoriation. When the secretion is very acid, dilute alkalis, as Sodium bicarb., may be employed in either hot or cold solutions.

Where the walls are relaxed and flabby, a solution of Zinc sulph., Aniodol, Alum, Chinisol, Sodium bicarb. Zinc chloride, Hydrarg. perchlor., Izal, Boracic acid, Salicylic acid, Tannic acid, Carbolic, or any tar preparations may give satisfactory results. One must vary the injection from time to time. In some cases great benefit is derived from starting the treatment with the daily injection of a tar preparation in warm solutions, and after four or five days using cold solutions of an astringent, as Zinc sulphate. I have had very good results with this treatment, and the daily irrigation of the vagina with quantities of cold water has given me very favourable results. The cold water appears to impart tone to

the relaxed condition of the tissues and also has an astringent effect. Protargol (which is a preparation of silver) is very effective in some cases.

One can vary the irrigation with spraying and tamponing.

To be successful the irrigations and tamponing must be carried out once or twice daily. The quantity of liquid used must be varied to suit the case, but it is essential that all exudate shall be removed at each dressing.

A generous diet, and in some cases a course of tonic and cooling medicine may be advised. But in all cases green food will be found beneficial, and if it is possible to get mares, affected with vaginal or uterine chronic inflammatory conditions, into paddocks of Sanfoin, Lucerne, Rye grass, or Clover, or even ordinary mixed green food, an appreciable improvement is soon evident.

Contagious Vaginitis. This is a condition that has been described by Dieckerhoff. It is a very acute disease, and frequently fatal, but those cases that recover are said to have a chronic vaginal discharge for a long period afterwards. The period of incubation is a short one, often twelve to twenty-four hours. The disease is said to be ushered in with symptoms of high fever, and acute inflammation of the vaginal mucosa. The inflammatory process is frequently associated with the formation of vesicles and ulcers. It often tends to involve the whole of the tissues of the vagina and not remain limited to the mucosa. Frequently it sets up a fatal peritonitis. In the acute form death often takes place in 48 hours, whilst in a less virulent form the case runs a more or less protracted course.

Treatment. This is practically limited to protective measures, attendance to the constitutional symptoms, and the rational treatment of the vaginal inflammation. (Dollar).

Growths in the Vagina. When the pressure of a tumour or polypus has been demonstrated, it is advisable to practise total extirpation, where it is possible. If the growth has a well marked pedicle this is easily accomplished, but if the base is diffuse it may be impossible to effect its removal, on account of its situation and risk of hæmorrhage. Abscesses and cysts are occasionally found in the walls of the vagina.

I have only seen two cases of vaginal abscesses, and in each of these my attention was not called to the mare on account of sterility, as both were pregnant, but were showing symptoms suggestive of abortion. The mare which was out at grass, was noticed to be dull and not feeding. She was brought in and placed in a box, when she was noticed to have a slight discharge from the vagina. She laid down and got up again at intervals, but did not attempt to roll. She occasionally strained and looked round towards her flank. I examined her and found a swelling in the roof of the vagina. It could also be felt through the rectum. I treated her with hot applications to the perineal region and the injection of warm solutions per rectum. The following day I evacuated the abscess, but the mare aborted. She had carried her foal for eight months.

In the other case the mare had been pregnant about seven months. The symptoms presented were practically the same as in the previous case. The abscess, however, was situated more anteriorly, and dispersed into the abdominal cavity, setting up a fatal peritonitis.

Cysts are sometimes encountered in the vaginal cavity. They can usually be evacuated. The presence of a tumour, polypus, cysts, or abscess in the vagina may cause symptoms of œstrum, or in the pregnant mare may induce abortion, or may present an obstacle to delivery.

Lacerations. In the vagina one often meets with portions of the mucous membrane hanging from the

roof or sides of the tube. In many cases no symptoms are manifested, but in others the free lacerated portion may act as a foreign body and induce nymphomania.

Treatment. Where the laceration or lacerated portion is small in extent no treatment is necessary, but if it causes the mare to be frequently in season it is advisable where possible to remove it. Caustics, absorbents, or stimulating dressings may effect this, but where their application is inadvisable the *écraseur* or other surgical appliance may be necessary.

The roof of the vagina is sometimes so extensively lacerated that it directly communicates with the rectum.

Relaxed Vagina. This constitutes the so-called ballooned condition, very frequently encountered in aged mares. It is sometimes associated with catarrh of the vestibule, or chronic inflammation of the cervix or uterus. The walls are very relaxed, and when the mare moves sharply or jumps, a peculiar noise is emitted, caused by the expulsion of air.

Treatment. If catarrh is present it must be treated on the usual surgical lines. The relaxed condition very frequently improves after a course of cold vaginal irrigations, with the internal administration of tonics and a good liberal diet. When the mare is making favourable progression the organ will be felt to respond to the hand when introduced, or will closely envelop the sides of the speculum. In these cases weak solutions of Zinc sulphate, Alum, and Plumbi acetate in copious cold injections have given good results.

It is not unusual to find the mucosa of the vagina of an unhealthy yellow or dirty grey colour, with localised or diffused patches of inflammation. When the inflammatory condition subsides, the mucosa gradually regains its normal colour, and the tone of the vestibule returns. In some cases the painting of the vestibule with weak solutions of iodine, or chinolol, is found beneficial.

Violent Muscular Contraction of the Vagina after Coitus. Often, in very excitable mares, as soon as the horse dismounts, the mare ejects the seminal fluid, and thus the service is rendered ineffective. Many cases of this abnormal muscular contraction are due solely to the mare's excitable temperament, but it is not rarely due to covering the mare when she is not ready for service. Large numbers of mares are very excitable for the first two days of oestrus, and will strain badly if covered at this period, but if the service is delayed for a day or so, the mare will often be perfectly quiet. These excitable mares should be exercised immediately after service, or placed in a closed box. Many mares will eject the semen if at once turned off into the paddock with other mares. When a mare persistently ejects the seminal fluid after coitus, it is advisable to practice artificial insemination.

Faulty Secretions of the Vagina. The normal secretion of the vagina is slightly neutral in reaction. Under various abnormal conditions the secretion becomes acid in reaction. The slightest tendency towards acidity at once renders spermatozoa inert. The presence of an acid reacting secretion of the vagina is a common cause of sterility.

Treatment. Internally, alkalis and tonics may be advised, and for the vaginal injection a solution of sodium bicarbonate usually gives the best results. The injection, which may be either hot or cold, should be carried out once or twice daily until the secretion becomes normal.

Ulceration of the Os Uteri. This is a frequent source of sterility. The ulceration may be restricted to a few small isolated spots, about the size of a millet seed, or it may be extensive involving the whole of the cervix. It is usually a sequel to chronic hyperæmia of the cervix. I have often observed extensive ulceration of the cervix and surrounding tissues, in mares that have foaled about a fortnight or three weeks, and in

these particular cases, the mare has invariably been in bad condition, with a not uncommon history of having been treated as a barren mare, and not fed in the way a mare should be whilst carrying a foal. In these cases more or less anæmia is present, and one can but conclude that the ulcerative process is associated with the anæmic condition observed.

On vaginal examination the ulcerated surfaces are seen as greyish or red looking patches, and there may be a slight discharge. In extensive ulceration in an aged mare the case is hopeless, but in a case treated early the condition often rapidly improves. It is more frequently seen in aged barren mares than in those under seven years of age.

Ulceration of the cervix has been ascribed to the interference with the lymph vessels in that position. As a result, the circulation becomes impaired, and localised patches of necrosis occur.

Treatment. The ulcerated surface is to be thoroughly cleansed with a warm solution of a mild astringent, and for a few days zinc sulphate may be used for preference. One then paints the ulcers with argenti nit. 10 per cent. every third day. Some of the milder forms require only two applications, and the after treatment consists in the daily sprayings of the cervix with an astringent solution, as zinc sulphate alone, or with plumbi acet. or alum. Chinolol gives satisfactory results in some cases after the ulcers have been cauterised with argenti nit. solution. To carry out the painting satisfactorily, a small camel's hair brush, with a handle about 18 inches in length is necessary, so that when the speculum has been introduced one can see the ulcers and more easily direct the application. A solution of iodine 10 per cent. or protargol, may also be used with advantage in some cases. Where diffused patches of ulceration are present, cold injections are preferable to warm ones. If the mare is low in condition good feeding and a course or tonic medicine may be followed with good results.

Hyperæmia of the Cervix. This condition is commonly found in aged barren mares, and in those that have not been covered for three or four seasons. It is also said to be caused by a change of climate.

It occurs as acute and chronic. The former, if treated, is usually only a temporary cause of sterility, whilst the latter form is usually permanent.

In acute cervical hyperæmia, the cervix and the surrounding tissues may be found to present a swollen and much thickened appearance. The opposed surfaces of the folds of mucous membrane may be adhering, and covered with a thick exudate. The cervix often presents the appearance of gelatinous infiltration, with small hæmorrhagic centres scattered here and there. There is often a thick mucus in the orifice of the os uteri, or the neck may be covered with exudate. The swollen condition of the cervical tissues is due to blood infiltration, and if it persists for some days, the exuded serum becomes plastic and a permanent thickening results.

In the chronic forms, ulcerative changes in the tissues of the cervix are very liable to supervene.

Treatment. In the acute form the injection of a warm solution of ac. boric or sodium chloride may be tried. The anterior portion of the vagina, including the *cul de sac*, may be packed with absorbent cotton wool to mechanically assist in the depletion of the engorged tissues. The cotton wool must be applied so that the tissues of the cervix are completely enveloped in the wool. The packing may be allowed to remain in position for six hours, when it should be removed and a copious warm boracic solution injected.

When the case tends to become chronic, the daily hot vaginal injections may be followed by the application of a weak solution of iodine every third day. Potassium iodide may be given internally. The mare, when it is

possible, should be placed on a grass diet and allowed plenty of exercise.

Deviation of the line of Cervix (flexion). The cervix is normally prolonged posteriorly in a horizontal direction, but one very often finds the line to be deviated towards the roof, floor or sides of the vestibule of the vagina, or it may be flexed on itself so that the os uteri is projecting anteriorly instead of in the posterior direction.

These abnormal positions, preclude the possibility of conception. The flexions are often due to contractions of the tissues, resulting from injuries, inflicted at times of parturition or during coitus.

Treatment. In all cases of badly flexed cervix, it is advisable to resort to artificial insemination.

Spasm of the Os. When one examines all the mares in a stud, that have been barren for two or three years, one not uncommonly encounters mares presenting this condition whilst in oestrus. The os is firmly contracted, and in these cases, it is advisable to make a thorough vaginal examination to determine whether the os is capable of remaining patent after dilatation has been effected. If the os quickly closes after relaxation has been brought about, it is advisable to insert a vulcanite tube into the os, immediately before service, and remove it shortly after if the mare is quiet. But if the mare is very excited, it is advisable to leave the tube in position for an hour or so. A pattern of tube for this purpose is made in various sizes. The tube is introduced as described above, and may be withdrawn by a tape which is attached to the side of the tube and left hanging outside the vulva. Where this method fails it is advisable to inseminate artificially.

The dilatation of the os is accomplished either by the application of a sedative as belladonna, hot compresses or continuous irrigation with hot water containing a sedative, by introducing a special dilator, or one can gradually dilate the os with the fingers after applying a sedative. Failing results from these measures one must resort to artificial insemination.

Indurated or Schirrous Os Not uncommonly seen in mares, which have received injury at time of parturition, the condition may be due to forcible extraction of the fetus before the os has fully dilated, and in rare cases from cicatricial thickening, the results of section of the os uteri when spasm has been present at time of foaling. It may also result from injury inflicted in the delivery of a very large fetus.

The lips of the cervix are tumefied and enormously thickened. In some cases the posterior portion of the cervix is not so badly affected as the anterior, and one may be able to introduce a finger for half an inch through the os, when a considerable obstruction may be encountered.

Treatment. Painting the indurated parts with iodine, and the internal administration of potassium iodide has been tried, but rarely produces beneficial results. When this condition is encountered at parturition, section is usually employed. In these cases it is always advisable to artificially inseminate after dilating the os.

Non-retaining or Relaxed Os. An abnormally relaxed os is often the cause of sterility. It may also be a cause of abortion. This condition may primarily be associated with injury, inflicted at time of parturition, or to a flaccid condition of the tissues of the cervix. In those cases due to injury, the healing process may have been completed, but the resulting cicatricial contraction may have caused the os to be widely dilated. In some cases the closed fist can be easily introduced through the os.

Treatment. If the relaxation is unassociated with laceration, but is present in a mare whose general condition is low, a course of nerve tonics might be advised, and daily irrigation of the vagina with cold astringent solutions practised. Surgical treatment is

very disappointing. In some cases I have practised artificial insemination, and then endeavoured to close the os by elastic ligature or plugging. In some cases the cervix is too short to admit of success of the first mentioned method.

Occlusion. The occlusion is most commonly caused by a piece of membrane overhanging or plugging the os; usually it is a portion of the cervical or vaginal mucosa, that has been lacerated during parturition and become partially detached, but in some cases the closure may be a result of an isolated tumefied portion of the cervix acting as a plug.

Treatment. Where the membranous structure is extensive, it is advisable to leave it, and resort to artificial insemination. In cases where the removal is deemed necessary, curetting, cauterisation, or extirpation may be practised. Tumours or polypi which obstruct the opening must be surgically removed, when possible.

Other Conditions. There are a number of conditions that may be taken together.

Disinclination for the male. Not coming into season; this may arise from various conditions, e.g., catarrh of the womb or vagina, dropsy of the womb, faulty development, degeneration or cystic conditions of the ovaries, weakness of the sexual organs as a result of breeding too early, phlegmatic temperament and proneness to put on fat, general weakness as a result of debilitating disease, nervous diseases affecting the spinal cord.

Treatment. Except in structural disease or malformations, the conditions must be treated on the usual lines.

The mare is often blamed when the horse is really at fault. The service may be incompletely performed, as a result of physical incapacity to perform the act, or from temper or excitement. The spermatic fluid may contain no spermatozoa.

In 1888 M. Repiquet contributed a report to *L'Ecole Vétérinaire d'Alfort*, in which he pointed out that 50 per cent. of the mares put to the horse annually remain barren, and that of these the majority have normal ovaries, but either structural or functional disease of the os uteri, and could be successfully bred from if artificially inseminated (*Veterinarian*, 1898).

Artificial insemination has been practised more in America than in any other country. It has obtained but slight recognition in France, Germany and Russia. English veterinarians have of late years taken up this branch of surgery. The operation is an easy one but strict attention to technique is necessary.

The instruments required comprise a vaginal speculum inseminator and an electric torch. There are various patterns of these instruments on the market. One may also require a vaginal dilator and a sponge-carrier. There are several patterns of inseminators in use in this country. I much prefer the metallic inseminators, and both the straight and curved instruments are necessary. One frequently sees a mare in which the cervix uteri is so flexed as to render the introduction of the straight inseminator quite impossible. The electric torch is very useful on dull days, but when there is a reasonable amount of light, one can dispense with the torch.

Modus Operandi. Having examined with the speculum and found the genital organs healthy, or noted any structural alteration, one proceeds to wash out the vagina with a dilute solution of the alkali. Some operators prefer a solution of permanganate of potash. I never use a disinfectant as I consider it is contra-indicated, and might possibly destroy the spermatozoa. Two buckets of clean water at the temperature of 100° F. are required. To one of these one adds a small quantity of bicarbonate of soda. The other bucket is required for the inseminator. A rubber bag is now sold that will closely envelope the inseminator so that that

instrument may be placed in the water, and kept dry and at the required temperature. The arms of the operator should be denuded up to the elbows, and be perfectly clean. A sponge, or three or four tampons of cotton wool, or tow, should be immersed in the alkaline fluid and then carried into the vagina, either by means of the hand or the sponge-carrier, and the whole of the vaginal and cervical mucosa lightly douched. When the operation is completed, no appreciable quantity of fluid should be seen. At the same time the os may be gradually dilated, when necessary, by gently rotating the hand.

Opinions vary as to the time this washing out of the vagina should take place. Some do so immediately before the service, whilst others advise that it should be carried out a few hours earlier. I prefer to carry out the process immediately before. Many owners are adverse to the use of the vaginal speculum, and the cleansing of the vagina prior to the service, as they believe a horse gives a mare a far better service without these preliminaries. But I am perfectly convinced, as a result of a number of experiments I have conducted, that this is fallacious, and furthermore, that the amount of semen left by the horse is in no way influenced by this process. It is advisable to carry out the examination, etc., in a box or yard where it is impossible for the horse to see or hear the mare, as many horses become very excitable and bad tempered if they can see the mare and are kept from her, and eventually the service may be a bad one.

It is always advisable to have the hobbles applied before the horse is permitted to cover the mare, as many valuable horses have been injured as a result of neglect of this precaution.

As soon as the horse dismounts after serving, the operator is to insert his left hand, and it is to be carried forward to the anterior portion of the vagina, where immediately behind and beneath the cervix, on the floor of the vagina, the semen will probably have collected. To aid this process, the fingers of the left hand may be depressed on the floor of the vagina at this spot. The inseminator is now introduced by the right hand. The index finger of the left hand should act as a guard for the nozzle which is directed into the pool of semen (if that is present), and the piston of the inseminator is withdrawn by the right hand. The nozzle of the charged tube is then to be introduced into the uterus, through the os uteri, and its contents discharged into that organ. By repeating this process another mare may be inseminated from the mare that has already been covered, if there is any spermatic fluid left in the vagina. There is a glass tube in the sides of the metallic inseminators so that it is readily seen whether or not any seminal fluid has been withdrawn.

There are several important points in connection with insemination, namely, the spermatic fluid must not be withdrawn from the vagina and exposed to strong rays of the sun; the whole operation should be carried out as speedily as possible; the inseminator is to be pushed quite through into the uterus before its contents are discharged; the inseminator is to be kept dry, and no water or air must be injected into the uterus at the time the semen is discharged.

With practice the smallest appreciable quantity of semen is at once recognised on introduction of the hand into the vagina. Very often when the semen ejected is small in quantity it may be found on the cervix or the lateral walls of the vestibule of the vagina. If no semen is found in the vagina, the act may have been improperly performed by the horse; no semen may have been ejected, or the semen may have been introduced directly into the uterus.

If it is inadvisable to cover a mare owing to the existence of injury to the back, excitable temperament, or

other reason, one can cover another mare that is in season, and inseminate from her.

The os of the mare that is to be covered may be plugged before service, or one may place an elastic ligature on the cervix.

Aphrodisiacs. In breeding districts, one is sometimes requested to artificially induce œstrum. Formerly the so-called Aphrodisiacs were advised, but at the present time neither veterinary practitioners nor the laymen have much faith in them. In America a proprietary article known as Vetol, which is said to be a preparation of Yohimbin, has been claimed to exert aphrodisiac effects. The Black Haw or Viburnum is also credited with such action. German veterinarians have written favourable accounts of the use of Yohimbin.

Breeders of thoroughbred stock like their mares to come into season the first three months of the year, although it is usual to cover thoroughbred mares from February until June—early in February preferably.

American veterinarians have for several years adopted the following method for inducing œstrum. The vaginal speculum is introduced and the os uteri is gradually dilated with a special dilator, the cervix is then painted with a solution of an irritant, and the mare is said invariably to come into season about the fourth to sixth day after the operation.

The CHAIRMAN said they were very much obliged to Mr. Castle for this exhaustive and most instructive paper which was almost beyond some of them.

The HON. SEC. said he desired to express his sincere thanks to Mr. Castle for coming forward to read a paper, and he was sorry the attendance was not commensurate with the importance of the paper, but many members were unable to be present. They would have the opportunity of reading it in the Veterinary papers, and many others not members of that Society would also read it with a great deal of interest, and gain much information from it. Their meetings in that way not only benefitted their own members, but also did good to the whole of the profession through the publication of papers and the report of the discussions. Everyone acquainted with secretarial work knew the difficulty of getting a paper, but Mr. Castle responded readily as soon as he was asked, in spite of the fact that he had been so recently elected a member.

With regard to the vaginal speculum Mr. Castle used, it would be rather interesting to know where it could be obtained. Another point was as to the methods of restraint Mr. Castle adopted when he was carrying out these various disinfective processes, and doing such things as putting an elastic band on the os uteri. Some mares were rather difficult to handle at all, and especially in an operation like that. He imagined one had to be pretty careful in applying sufficient restraint. Then a very exhaustive list of antiseptics which could be used was given. It would be well to know which, from his extensive experience, Mr. Castle considered the best. If he would inform them what he generally used it would be some guide to the members as to what would be likely to meet with the best results.

The CHAIRMAN said he would like to ask what strength of aniodol he used, also what strength he made the solution of silver nitrate, and whether he had used any Chinosol pessaries for catarrh. He had used them himself and found them very successful.

Mr. FAITHFULL asked whether, when he had a case for daily washing out, Mr. Castle had the mare at hospital.

Mr. CASTLE said he had described what he saw in stud work.

Mr. FAITHFULL asked whether in private cases a groom could be allowed to wash out, or should a call be made for it.

Mr. CASTLE said one must take into consideration what kind of man the groom was.

Mr. FAITHFULL asked whether a working mare would be taken into hospital.

Mr. CASTLE said he would if the case was worth treatment, and the owner was willing to spend money on it.

Mr. AUGER said he had not had sufficient experience to discuss the paper, but Mr. Castle appeared to have given immense attention to the subject, and indeed could be called a specialist in it.

Mr. FAITHFULL said that very often a man would tell them he had got a mare that would not stand the horse, but he never thought of asking them to come professionally and do something.

Mr. AUGER asked what form of insemination Mr. Castle had used.

Mr. CASTLE replied that he liked the metal speculum best, and the pattern he used was Polansky's which he had met in several studs. It was inserted sideways and turned over. There was a big iron trough at the bottom, and the arms went up to dilate the os so that a very good examination can be made with it. As to Chinosol pessaries, he could only say he had used iodoform boracic with very good results. For painting ulceration he used Argenti. nit. 10 per cent., varying it with Iodine, but he was a great believer in Zinc sulphate for these cases. One point he omitted to mention in his paper as to the dilation of the os, he had heard that when the Arabs had a mare they could not breed from which they thought might be due to contraction of the os, they galloped her till she was breathless then covered her at once. It might be due to constriction of the os which got into a relaxed state when the mare was breathless.

As to restraint, he had had his hand in as many as 20 mares in one day, and the only precaution he took was a twitch and limb up. He never found he had to do more than this. Every mare covered always had the twitch and hobbles on. As regards the ligature business, this was very disappointing, useless, and unsatisfactory. He did not think there was any danger in handling mares in the way he had described. As to disinfection, if Mr. Smith wished to know what really seemed to him the best uterine and vaginal disinfectant, he strongly believed in Zinc sulph. for what was known as a dirty womb, alum and lead also gave good results. He used 5 grains to the ounce of Zinc sulph. The inseminators he preferred were the metal ones, and they could be had either straight or curved.

The HON. SEC. asked if Mr. Castle could state the percentage of successes obtained by insemination?

Mr. CASTLE said that unfortunately, in the large majority of cases the mares they got had been barren for a number of years. Unless one could get at a mare so as to dress the womb regularly, they could not get very good results, because although the mares might be inseminated, the womb might not be in a fit condition. It was claimed by the people who sold the instruments that they got 90 per cent., but if a man got 40 per cent. of really barren mares in foal he would be doing uncommonly well. "Sandflake filly," which made a very high price, was got by insemination. The inseminator was all right as long as the womb was healthy and there was no physical deformity, but when there was any catarrh they must not expect success. Sometimes he had gone three or four times before he could get a womb into anything like condition for covering the mare.

Mr. FAITHFULL moved a vote of thanks to the essayist and to the Chairman, which the Hon. Sec. seconded.

Mr. CASTLE briefly replied, and the Chairman said he was always pleased to be of any use to the Society. It was a great pleasure to hear such a paper, but he hoped their next meeting would be more largely attended.

The Tuberculosis Order of 1913.

At a meeting of East Lothian County Local Authority under the Contagious Diseases (Animals) Act, Mr. T. Elder, Stevenson Mains, presiding, a report was submitted regarding the working in the county of the Tuberculosis Order, 1913. It was reported that five animals had recently been slaughtered by the Board, these being in three places in the county. The cases had occurred mainly in the eastern district. In one instance the proprietor of an animal had, as was within his rights, the animal slaughtered at his own instance. No compensation is paid in such a case. In another instance a fine heavy cow had been slaughtered owing to udder tuberculosis. It had been valued before slaughter at £15, and the sum obtained for the carcase and hide left a balance in hand over expenses and compensation due. The Board agreed that in such a case the spirit of the Act was that the surplus should be paid to the owner of the animal, and it was agreed the Board should adopt this principle.

It was reported that seven ponies which had reacted under the Mallein test, in connection with the outbreak of glanders in Prestongrange Colliery, had been slaughtered. On post-mortem four of the carcasses showed clinical symptoms of glanders and three did not. The Board agreed to pay £66 compensation out of a valuation of £94 for the ponies.

Mr. William Henderson, of Lawton, presided at a meeting of the Local Authority of Perthshire under the Diseases of Animals Acts, which was held at Perth on Friday, 8th inst. Further communication from the Board of Agriculture and from the Treasury were read in reply to representations for amendment of the Tuberculosis Order, 1913, from which it appeared that the representations were ineffective. After discussion, it was agreed to put the Order into operation and to appoint the veterinary inspectors already in office to carry it out, it being remitted to the Emergency Committee to meet with the inspectors and arrange as to terms. —*The Scottish Farmer*.

The official gazette of the County Councils Association contains the following:—

"The Board of Agriculture and Fisheries have given the undermentioned replies to questions addressed to them by the Notts County Council:—

1. DISCRETION OF LOCAL AUTHORITY.

*Question:—*Can the Local Authority exercise any discretion in regard to slaughter if they are advised that the tuberculosis from which the animal is suffering is not of an infectious character?

*Answer:—*The obligation of Local Authority to slaughter is regulated by Article 5 of the Order, and is not affected by any advice to the Local Authority as to whether the tuberculosis is or is not of an infectious character.

2. TUBERCULIN TEST.

Question:—(a) Are the Local Authority bound by the results of the tuberculin test, which they are informed is not always reliable?

(b) If any bovine animal appears to be in good condition and not emaciated, but reacts to the tuberculin test, is such an animal to be slaughtered, if notice is sent to the Local Authority under Article 3 of the Order?

*Answer:—*The fact that an animal reacts to the tuberculin test does not necessarily involve its slaughter, but the evidence so afforded, when it has been necessary to apply the test, must be considered in connection with any other evidence available to show that the animal falls within the scope of Article 3. If an animal which

is neither an emaciated animal nor a cow should happen to be tested with tuberculin and react, it will not be slaughtered under the Order.

3. COMPENSATION.

Question:—Is it absolutely certain that the Local Authority will receive a sum equal to half the value of the animal slaughtered in accordance with Article 8 of the Order, or is there a probability of this amount being reduced if the claims to the Board exceed the amount allowed by the Treasury?

Answer:—The undertaking to repay to Local Authorities from the Exchequer one half the net cost of compensation for animals slaughtered under the Order is not limited in the sense implied in the question, and the Board have no reason to anticipate that the undertaking as given in their circular letters of the 17th February and 25th March will be withdrawn or qualified without due notice.

The Board have also given the following information upon the question of salvage: In Form B (the summary account of the compensation paid for animals slaughtered) the Local Authority are required to deduct salvage received from the carcasses or parts of carcasses of slaughtered animals.

The sums to be brought to account are the net proceeds after deduction of expenses incurred in the salvage of carcasses.—*Local Government Chronicle*.

"Referred Back."

At a meeting of Cornwall County Council at Truro on Wednesday, 13th inst., Mr. Boscawen said the Contagious Diseases (Animals) Committee asked that the

bill of Mr. Langdon, veterinary inspector of the Camel-ford district, be referred back.

Mr. Buller Howell said Mr. Langdon was under the impression that he had to apply the tuberculin test to all animals found ailing. Hence the large amount of his bill, £88 5s.

The Clerk (Mr. Cowlard), in reply to Mr. Bazeley, said the Order stated that the tuberculin test was only to be applied where absolutely necessary.

The bill was referred back.

The "Poisons Act" in New Zealand.

CORROSIVE-SUBLIMATE SOLOIDS.—A few weeks ago Sir Robert Stout gave judgment in a case heard at Palmerston North on an appeal from the decision of Mr. A. D. Thomson in the Lower Court, holding that soloids or pellets of corrosive sublimate used extensively by dairy farmers as a disinfectant drench for cattle could be sold without an entry being made in the poisons book. The Magistrate held that they are preparations for which the entry is not required. It was pointed out during the hearing that the Department of Agriculture distributed thousands of these soloids annually, and that in the Palmerston district 25,000 have been sold in a season, chiefly by post. His Honour remarked that the soloids consist of 8½ grains of corrosive sublimate, ¼ grain of colouring matter, and about 3 grains of adhesive material. Even if it were held that the soloids are a preparation, that does not prevent them from being also corrosive sublimate itself. He held that they come within Part 1 of the Poisons Schedule.—*The Chemist and Druggist*.

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

The Horse not yet Extinct.

There was a great gathering at Dunure Mains on Wednesday, 13th inst. The occasion was the annual outing of the students attending the continuation classes conducted in Lanarkshire by Mr. Jas. M'Cutcheon, of the West of Scotland College of Agriculture. Whenever it became known that Mr. William Dunlop had agreed to welcome the young men, and to show them his magnificent stud of Clydesdale horses, there was a general desire in all the districts to take part in the excursion, and over 200 of the members of the classes attended. Lesmahagow sent 40 students, East Kilbride 34, Strathaven 50, Carnwath 40, and Slamannan 30. In addition, about twenty young men who are attending demonstrations given by Prof. J. R. McCall, of the Glasgow Veterinary College at Holmes Farm, Kilmarnock, were also given the opportunity of attending.—*The Scottish Farmer*.

As good as a V.S.

A case of cruelty to a horse was before the King's Heath (Birmingham) magistrates on Tuesday, the defendant being Ernest Rudge, of Halesowen. It was stated that a horse belonging to defendant had been injured, and an attempt had been made to stitch up a large gaping wound with an ordinary needle and thread. The stitches had been placed so near the edge of the wound that they had broken away.

Rudge, who considered he had done as well for his horse as a veterinary surgeon, was fined 20s. and costs, the Magistrates thinking he had erred in ignorance.—*The Daily Telegraph*.

Annual Parade at Canterbury.

The Tenth Annual Parade of the Corporation employees took place in the Cattle Market, on Thursday, 14th inst. There was a very large attendance, and the judging was once again in the hands of the trio who have so ably discharged this duty for the past nine years, viz., Messrs. W. H. Crowhurst, F.R.C.V.S., G. M. Goodson, and R. W. Wood. During the afternoon there was a good muster of the members of the Corporation and officials, including the Mayor (Mr. G. Mount).

Mrs. W. H. Crowhurst was also an interested spectator.—*Kent Herald*.

"Sweet Bloom."

At West Linton Show, on Saturday, 9th inst., the second prize in the Clydesdale brood mare class was awarded to "Sweet Bloom," belonging to Mr. H. D. Lorimer of Callands. The class was strong, and had the mare not been looking rather thin as the result of a cold she would, in the opinion of many good judges at the ring side, have deserved the red ticket. This mare is exceedingly well at present and thoroughly sound. Doubtless many will recognise in "Sweet Bloom" the filly which was the subject of litigation in what was known as "The Ringbone Case" in the Sheriff Court at Dumfries, and afterwards in the Court of Session in Edinburgh.—*Dumfries and Galloway Herald*.

Irish Horses for the Greek Army.

The Greek steamer Assos arrived in the Shannon for the purpose of embarking some 400 horses which have been purchased mainly in Limerick and South Ireland for the Greek Government. The horses are for army purposes.

Bowls at Woodbridge—V.V.B. Fund.

Last year Mr. T. G. Heatley established a precedent in Woodbridge by linking the game of bowls to a charitable object. He invited entries for a Bowling Tournament which should be played on his lawn—a beautiful piece of turf—and gave the entrance fees to the Victoria Veterinary Benevolent Society.

The promoter was so pleased with the number of entries—thirty-three—that he decided to repeat the experiment this year, and fifty-two players put down their names to play. This increased number certainly means an increased call upon Mr. Heatley's hospitality, but as it means a larger amount for the Benevolent Society it almost goes without saying that Mr. Heatley's pleasure goes up automatically.

A pair of bowls of the value of not less a guinea were offered for the first prize, and a silver spoon for the second prize was given by W. Shipley, Esq., Hon. Sec. of the Society. Mr. Shipley was present at the competition in the dual role of Secretary and player.

FOURTH ROUND.

L. W. Hayward 11, R. Smith 9.
O. Thurlow 11, E. G. Green 10.
G. Giles 11, G. Chandler 7.
H. Hazelwood 11, J. F. Thurston 7.

SEMI-FINAL.

O. Thurlow 11, L. W. Hayward 9.
G. Giles 11, H. Hazelwood 5.

FINAL.

G. Giles 11, O. Thurlow 6.

This was a strange game. Thurlow got the first 6 points and never scored again.

Amongst the players were: T. W. Smith, J. F. Thurston, H. E. Wilkinson, T. G. Heatley, W. Shipley, and W. Turtill.

Mr. Shipley writes:—I am pleased to say I have received a cheque value £5 4s. 6d. from Mr. Heatley, being the proceeds of the Bowling Tournament, which will again help us to forward the objects of our Fund.

Personal.

ANDREW—URE.—On 16th August, at Ware, Archibald Houston Andrew, M.R.C.V.S., to Marianne Prentice Ure.

Mr. W. LOGAN, M.R.C.V.S., Inverness, was judge of the Light-legged horses, at the annual show of the Central Banffshire Farmers' Club, which took place at Keith on Tuesday, 12th inst.

Mr. ALEX. POTTIE, junr., M.R.C.V.S., Paisley, was one of the judges of the Light-horse Class at the annual show held under the auspices of Arran Farmers' Society at Lagg, on Wednesday, 13th inst.

Mr. DAVID ALLAN, M.R.C.V.S., Clarkston, Busby, judged the Light-legged horses at the annual show of the Biggar Farmers' Club, held on Thursday, 14th inst., at Biggar.

OBITUARY

JAMES G. BURDEN, M.R.C.V.S., Southampton.
Graduated, Lond: Dec., 1879.

Mr. Burden's death occurred on August 16th, from carcinoma of intestine. Aged 65 years.

CROWHURST.—On Aug. 18th, at The Pleydells, Sturry, Isabella Rosina, the dearly loved wife of James Crowhurst, F.R.C.V.S., and younger daughter of the late Capt. Samuel Frederic Short, Royal Navy, and granddaughter of the late Capt. John Robert Benson, Royal Navy.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1312.

AUGUST 30, 1913.

Vol. XXVI.

THE STATE CONTROL OF TUBERCULIN.

There is an increasing desire in our profession that tuberculin should be placed under State control in two particulars. One is that it should be standardised, so as to be of uniform activity; the other is that its use should be limited to veterinary surgeons. Both are so obviously desirable that we seem in some danger of losing sight of the question of whether either is possible; for veterinary societies pass resolutions supporting them almost as matter of course, with little discussion of their practicability.

Undoubtedly the standardisation of tuberculin would be a good thing, if it could be accomplished. Many private firms and some institutes manufacture tuberculin; and it is well known that the products of different makers are not all of equal potency. But by what legal provisions could the standardisation be accomplished? And could it be accomplished at all without conferring something approaching to monopolies upon a few manufacturers? Without discussing the latter plan, it may be said at once that no British Government would be at all likely to adopt it. This question of interference with vested interests is a serious one; and it is not the only difficulty in the way of the standardisation of a biological product such as tuberculin.

The proposed limitation of the use of tuberculin to veterinary surgeons might be more easy to attain, so far as the mere legislation for it is concerned. But is it likely that any such legislation could be enforced? Of course it would be illegal for laymen to buy tuberculin from abroad and use it; but they could, and would, do so undetected perhaps to a considerable extent. Further, while such legislation would not stop the lay use of tuberculin, it would have the effect of rendering it an absolutely secret practice, which it scarcely is at present—and possibly also tend to systematise it. Ill-considered legislation is apt to defeat its own object; and it seems possible that such legislation as this might even increase rather than diminish the fraudulent use of tuberculin.

A tuberculin of uniform strength in use throughout the kingdom, and available only to veterinary surgeons, would enable us to work under ideal conditions. That may be granted without question; but is it likely that such conditions can ever be obtained? Before making a serious attempt to obtain them, we should do well to carefully consider the practical difficulties that may check us.

SPASM OF THE LARYNX?

I have encountered two cases of this condition, both calling for the prompt operation of tracheotomy. Both occurred under the same conditions of work and weather—work in the hayfield on very hot days. Both appeared to be cases of pure, uncomplicated spasm, as after obtaining relief by tracheotomy the animals were in a short time able to breathe comfortably through the larynx when the hole in the trachea was temporarily closed.

Case I. Subject.—A light cart mare, had been drawing a hay rake.

July 15th, 1907.—This animal was reported to be breathing with difficulty and making a loud noise. I found her obviously distressed, and making a considerable noise during inspiration; membranes very cyanosed. As there seemed no likelihood of a foreign body being present in the pharynx or larynx I diagnosed spasm of the latter, and tried injections of morphia, with liniment externally; getting no relief, and the membranes becoming more cyanosed and mare more distressed, I fetched a tracheotomy tube, etc., as quickly as possible. Returning in a few minutes I found the mare off her legs, so dispensing with any antiseptic preparations I hastily opened the trachea and inserted the tube. In a few minutes the breathing was normal, the membranes a more natural colour, and the mare able to rise. I found on closing the tube the mare was again able to breathe comfortably through the larynx.

Case II. Subject.—A powerful cart horse, nine years old, had been helping to draw a mowing machine.

August 2nd, 1913.—I received a telegram "Come at once, accident in hayfield," consequently I went prepared for wounds, etc., but not "tracheotomy."

I found this animal very distressed, breathing with great difficulty, membranes very cyanosed, but noise was not so noticeable as in first case. Tracheotomy was urgently necessary, and I made hasty preparation.

On lifting the horse's head slightly, to expose the trachea, he fell down, and the operation had to be performed in the recumbent position. Unluckily the animal fell on a heap of dust, and I had visions of septic trouble, but the breathing had practically stopped, and there was no time to move him.

After holding the trachea open with my fingers for a few minutes the horse was able to rise, and I improvised a tube from a piece of lead tubing.

As in the first case, I found the obstruction to the breathing had passed away after a few minutes, and so far as I know there was no recurrence in

either case, although I kept the temporary tubes in for a day or two as a safeguard.

I had the mare under observation for three years afterwards, but she had no return of the trouble, continued to work normally, and I could not detect any obstruction to her breathing, the horse on the other hand, I was given to understand, had been a roarer for some time.

As in neither case was there any coughing to clear the larynx, etc., I conclude these were cases of spasm pure and simple.

HERBERT E. WHITEMORE.

Langport, Somerset.

TETANUS.

About two months ago a seven-year-old Shire mare was sent to be shod and returned with a wound on the right side of the loin. A fortnight later I was asked to see her as they thought she had hurt her back. I found her with nose poked out, ears pricked, tail erected, haw crossing over the eye when head was raised, her hind legs were straddled wide apart, jaws not quite closed. Having some anti-tetanic serum by me, I injected a full dose at the seat of injury. We kept her in slings for five weeks, during which time she stood with hind legs as far apart as ever she could get them. The muscles were very rigid, and she could not move them forward or backward. Her jaws never completely closed, and she fed well all the time. Eventually the rigidity left her tail, she gradually regained the normal use of her legs, and she is now at work in the team.

CHLOROFORM STANDING.

I treated three horses by this method; the first, a heavy Shire stallion, which they could not shoe standing. He took three ounces and went down quietly. He was never any trouble to shoe after this.

Second. A Shire gelding; operation, poll-evil and fistulous withers. He was no trouble.

Third. Last Thursday morning a seven-year-old hunter was sent to be unnerved in the off fore leg for navicular disease. We put two ropes round his neck with two men on each side to steady him.

I put chloroform into the muzzle (air excluded). The place in which we were going to operate was a combination of an orchard and garden. As soon as he got a smell of the chloroform he started off full gallop, and we could not hold him; he went full tilt over some young apple trees, through a row of sweet peas and a tomato bed, knocked one of the men down and broke his finger. I managed to get my rope round a plum tree, and he kept on full tilt round the tree until he wound himself up, taking all the skin off my knuckles. We had put the instruments behind this tree; he galloped over the tray two or three times scattering the instruments, etc., and breaking the chloroform bottle. When he finished

up he was about half chloroformed, and as I had no more handy he came to again. We cast him with the hobbles and chloroformed him down. After the operation he ate a mouthful or two of hay, then began to blow and retch, bringing up mucus through his nostrils; he kept this on for about an hour and then recovered.

He left for home yesterday, sound and all right. When I want to chloroform another horse I think I will put him down first.

J. H. PARKER, M.B.C.V.S.

Faringdon.

CANINE DISTEMPER.

With reference to a paragraph from *The British Medical Journal* which appeared in *The Record* of June 21st anent the causal organism of canine distemper, I thought it might be of some interest to mention that the Director of the Pasteur Institute at Kasauli—Capt. Acton, I.M.S., has informed me recently, that some three years he noted amongst his experimental rabbits, whose numbers vary between 500 and 1000, a fatal epidemic occurring annually or bi-annually, generally at the end of the rainy season or commencement of the hot weather. The condition he believed was identical with canine distemper, the symptoms and course of the disease being in every respect similar.

Proceeding to investigate, he isolated from the trachea of rabbits dead of the condition a coccobacillus, and this he had no difficulty in growing at 35° C. on agar.

Injection of this material into young healthy dogs and kittens set up a condition in them similar to canine distemper and to the epidemic amongst the rabbits. Adult dogs and cats were refractory.

Proceeding further, Captain Acton prepared a vaccine from the material, and it is now the custom at the Institute on the approach of the infective seasons to vaccinate young or any rabbits that it is intended to carry over for some months—or at least those that will not be required for immediate experimental work. The results have been excellent, the disease having, I understand, practically disappeared from the hutches.

In conclusion, I may note that this seems to confirm the contention of McGowan, Ferry, and others.

L. J. KELLY, M.R.C.V.S.

Calcutta.

ABSTRACTS FROM FOREIGN JOURNALS

THE PATHOGENICITY OF THEILER'S TRYPANOSOME.

Vryburg has published (*Tydcshr. v. Veeartsenijkunde*) an article upon this question. It is very probable, he says, that the trypanosomes discovered in healthy cattle in different countries belong to the same species. Laveran makes a distinction between the trypanosome of Theiler and the Transvaalian

trypanosome; but Vryburg is convinced that they are only two varieties of the type *T. Theileri*.

It is generally admitted that this parasite is not pathogenic; for the cattle in which it has been found (either by direct examination of the blood or by cultures) present very few morbid symptoms, or show symptoms which may be attributed to other causes. Theiler, having found the parasite in cattle affected with biliary fever, assigned a pathogenic rôle to it; but, at a later period, he considered the trypanosome to be an occasional parasite, and recognised that the disease of biliary fever is due to a parasite of the red blood corpuscles, which he named *Anaplasma marginale*.

Theiler also found the trypanosome in cattle affected with rinderpest.

A great number of workers have experimented with Theiler's trypanosome; and Vryburg concludes from their results, that if the parasite does not generally produce morbid lesions, we nevertheless cannot be assured that it is totally inoffensive.

When the parasites are so few that direct examination of the blood fails to reveal their presence, they cause little disturbance. When they are more numerous, they induce fever and engorgement of the spleen and lymphatic glands. If the temperature is not taken, the affected animals may only show slight objective symptoms; but it is none the less true that, in subjects attacked by another disease, chronic trypanosomiasis may become acute and engender serious and even mortal disturbances. Vryburg therefore thinks that Theiler's trypanosome, which is found in at least 27 per cent. of Dutch cattle over two years old, should not be considered as a negligible quantity.—(*Annales de Méd. Vét.*)

TRYPANOSOMES FOUND IN A COW IN ENGLAND.

A. C. Coles (*Parasitology*, 1913, Jan., vol. 5, No. 4, pp. 247—252) after summarising the literature that has appeared on the occurrence of trypanosomes of the *theileri* type in the blood of cattle, describes two specimens found by him in the blood of a cow in Dorsetshire.

At the time when the trypanosomes were found, the animal was the subject of redwater, *Babesia bovis* being present in the blood and about 2 per cent. of the blood corpuscles invaded. Two parasites were found in one blood film out of seven examined, and none were found in 20 films made two days later.

The trypanosome measured 98 microns in length including the flagellum. The body measured 88; the flagellum 10; from the posterior extremity to the kinetoculus 37, and to the centre of the trophoculus 44; the diameter of the body 6; and the width of the undulating membrane 3.5 microns.—(*Tropical Veterinary Bulletin*).

EPIZOOTIC MYOCARDITIS OF THE SHEEP.

J. Lesage, in a communication to the Academy of Sciences, describes a disease which he designates by the above name. It is a malady of infectious character, which raged at the commencement of this year amongst several flocks of sheep (South-

down crosses) in the Cote-d'Or district, causing a great mortality.

In one of the flocks the disease appeared at the end of January, and in less than three months destroyed sixty of that year's lambs (the total number of lambs in the flock being 130). The ewes suckling the affected lambs did not contract the disease. On the other hand, the ram which was the sire of these lambs was affected, and may be regarded as the cause of the disease in the lambs. The ram was six years old, and had been introduced into the flock the year before. He had always been in bad general condition, and had been subject to recurrent attacks of vesicular eruption of the lips, œdema of the subglottal region, lachrymation, and evident signs of debility. He was slaughtered during the course of the epizootic, and showed the same post-mortem lesions as the lambs.

Two very apparent symptoms observed in the course of the disease in lambs are an ulcero-membranous stomatitis and disturbances of locomotion. Both these signs may be absent; but there is one post-mortem lesion which is absolutely constant, viz., a degenerative inflammation of the cardiac muscle. The constancy of this lesion justifies the designation of the disease which the author employs, until the etiological rôle of the protozoa he has observed is definitely settled.

The ulcerous stomatitis, which generally precedes the troubles of locomotion, resembles in its symptomatology the affection which is commonly called *brouton* or *muguet* of lambs, the causal microbe of which has not yet been discovered. It is an ulcerative inflammation of the buccal mucous membrane, with the production of a pultaceous whitish deposit. The initial lesions are small perfectly round vesicles of from 1-12th inch to 1-8th inch in diameter, and may be either isolated or confluent.

The disturbances of locomotion consist in a kind of paralysis, which obliges the animals to lie down after walking a few steps, and renders it impossible for them to rise unaided. The lambs, thus confined to the ground, show no acute suffering; they bleat to call their mothers, and, if helped to their feet, take the teat and feed with appetite. They all show constipation.

In rapidly progressing cases, death occurs in two or three days; in others, only at the end of a month or two, the course of the disease in these latter cases being marked by relapses. These are cases in which death occurs suddenly, in animals which have been believed to be completely cured.

Post-mortem, the liver is hypertrophied and discoloured in many cases. The spleen and the other organs, except the heart, have a normal appearance.

The alteration of the heart involves neither the pericardium nor the pericardial fluid; but the myocardium is invariably the seat of important lesions of degeneration. The external aspect of the cardiac muscle presents a spotted appearance, particularly at the point of the organ and in the neighbourhood of the coronary arteries. The spots are yellowish in colour, and contrast with blackish

hæmorrhagic zones; they are either punctiform or extensive, and are distributed irregularly over a surface of a few centimeters. Upon section of the wall of the heart, the naked eye can see that these spots represent yellowish islets involving a quarter or even a third of the thickness of the wall. The point of the heart is often very thin, and reddened internally.

Internally, the auriculo-ventricular and sigmoid valves are very œdematous and bright red in colour. The spots of degeneration are more numerous and more extensive; and at these spots the endocardium is destroyed.

Microscopic examination of sections of the myocardium under a high power shows that the degenerating cardiac fibre becomes hypertrophied and then loses its transverse striation, while at the same time most of its nuclei become segmented by direct division. These nuclei, simple or divided, then become surrounded at the expense of the fibre by a transparent substance which is the product of the degeneration. The process is therefore really one of absorption rather than of inflammation.

Cultural experiments have been made upon the usual media with blood (even in large quantities), with liver-pulp and spleen-pulp, and also with the degenerative substance of the heart. All these have yielded negative results.

On the other hand, microscopical examination of scrapings from the buccal lesions and the hepatic parenchyma has revealed the presence of two interesting protozoa. The first is a spirochæte, which is found in the lesions of ulcero-membranous stomatitis in all the affected animals; the second is a flagellated organism which exists in the hypertrophied liver. Without prejudging the relations which may be established between the two organisms, and without yet being able to affirm that they are veritable agents of the disease, the author describes them as follows:—

The *spirochæte* appears in the form of long undulating filaments, very thin, tapered at the extremities, and forming a spiral, the length of which varies from 12 to 30 microns, with a thickness of from 0.1 to 0.4 micron. The ordinary number of curves of the spiral is from three to four for the most common forms (those about 15 microns long); but it is from 8 to 10 for longer forms which are undergoing division. The organism takes stains with difficulty, and remains very pale in preparations made by Giemsa's method.

The *flagellate* organism of the hypertrophied liver should be compared with the parasite described by Rivolta in 1881 under the name of *monocercomonas hepatica*, and discovered in the livers of young pigeons. It stains easily by Giemsa's method.

It is destitute of an undulating membrane. Some of its forms are fusiform, and provided with two flagellæ situated at the two extremities of the protoplasmic body. Others are round in shape, and are without prolongations. The *fusiform* organisms have a length of from 2 to 4 microns without the flagellæ, each of which is from 3 to 4 microns long. The protoplasm of these forms is granular, and the nucleus is diffuse. The *round* forms have nearly

the dimensions of red blood corpuscles; their nuclei are better defined than those of the fusiform organism, and form variable figures.

These round forms are often seen in masses comparable to those which have been described in connection with the trypanosome of the rat under the name of *pseudo-leucocytes*.—(*La Semaine Vétérinaire*).

W. R. C.

A STUDY OF THE NORMAL BLOOD OF THE CARABAO (BUFFALO).—W. H. BOYNTON. (*Philippine Bur. Agr. Bul.* 21, 1912, pp. 12).

Twenty-five animals in normal condition, from 2½ to 6 years of age, were used in the studies here reported.

In the circulating blood of supposedly normal carabaos over two years old the red corpuscles were found to average 6,057,520 per millimeter. The average percentage of hemoglobin was 92.6. The average number of leucocytes was 10,389 per cubic millimeter. The average specific gravity found was 1.0532. The relative volume of corpuscles to plasma was found to be 29.1 per cent. of corpuscles to 70.9 per cent. of plasma.

The average time for complete coagulation of the blood was found to be three minutes and 16 seconds plus.

Of the five varieties of leucocytes found in the peripheral blood, 48.5 per cent. were lymphocytes, 4.6 per cent. large mononuclears, 34.5 per cent. polynuclears, 11.5 per cent. eosinophiles, and 12 per cent. mast cells.

THE INFECTIVITY OF PARTS OF ORGANS OF GLANDERED HORSES, THE COMPLEMENT FIXATION REACTION WITH GUINEA-PIGS, AND SOME CURATIVE AND IMMUNIZING TESTS.—H. MIESSNER (*Centbl. Bakt. etc. I, Abt., Orig.*, 64, (1912), *Festschrift f. Loeffler*, pp. 121-151, pl. 1).

Only one quarter of the guinea-pigs infected with pieces of the organs of glandered horses became glandered. According to this, the results obtained with the infection test must be interpreted with care. Guinea-pigs infected with defibrinated blood rarely took the disease. Guinea-pigs infected with either the organs or blood of glandered animals can only be considered glandered when the findings of the complement fixation test have been confirmed by the autopsy findings, or the animals have gone through the course of a light form of the disease during their lifetime. Therefore the complement fixation tests cannot be relied upon.

Guinea-pigs were treated with mallein or a killed culture of glanders bacillus for the purpose of determining whether the serum of these animals behaves as does that obtained from horses pre-treated in the same way. This was answered in the affirmative with the aid of the complement fixation test. Artificial and natural gastric juice did not seem to have any particular bactericidal action for the glanders bacillus. Glanders bacilli placed directly in the stomach of guinea-pigs produce glanders in these animals. Horses which were fed cultures of

bacillus mallei, given with the food, did not contract the disease.

Immunizing tests with antiformin solutions of the glands bacillus and guinea-pigs showed that a single or a double treatment (given subcutaneously or intra-abdominally) did not produce an immunity in these animals. The salvarsan treatment was not effective for glanders.

MORTALITY OF STOCK ON MANGELS.—C. ASTON
Jour. New Zeal. Dept. Agr., 3 (1912), No. 3, pp. 214-215; *Vet. Jour.*, 68 (1912), No. 445, pp. 425-427.

The author reports briefly on investigations conducted following the loss in August of cattle and pigs which had been fed on mangels. Analyses of these mangels made during September showed the juice to contain 0.06 per cent. of nitrogen as nitrites and nitrates. Nitrites were present in traces, a fact which seems not to have been recorded before in mangels, although mentioned as being found in other plant juices in small amounts. "The amount of nitrogen found is equivalent to 0.43 per cent. of potassium nitrate, and a cow eating 60lbs. of mangel juice would consume 116 gm. (4 oz.) potassium nitrate (mangels contain 95 per cent. of juice)."

F. E. P.

FILTER PASSERS.

At the Seventeenth International Congress of Medicine, in Section IV., Bacteriology and Immunity, under the presidency of Prof. G. Sims Woodhead, on Monday, Aug. 11th:—

Prof. F. LOEFFLER (Greifswald) opened a discussion. He said that since he and Frosch showed in 1898 that the virus of foot-and-mouth disease passed through filters a large series of diseases had been attributed to "filter passers." Amongst these might be mentioned yellow fever, dengue, pappataci fever, poliomyelitis, and infective pleuro-pneumonia of cattle; recently it had been asserted that the infective agents of scarlet fever, measles, and typhus fever also belonged to this group. He pointed out that the capacity of a virus to pass through a filter told nothing of its nature except that it must be of minute size. The virus could be characterised only by its power to reproduce the disease on inoculation. Attempts to cultivate the filter passers in artificial media had in general been unsatisfactory; but success had been achieved in certain instances. Thus, the virus of infective pleuro-pneumonia was cultivated inside collodion sacs in the peritoneal cavity of rabbits, and Bordet obtained growths on blood agar. The parasite in this instance was relatively large and its filtrability was prevented if there was too great an amount of albumin in the fluid to be filtered. The fowl plague virus also grew in artificial media, as was proved by the fact that the minimal infecting dose was the same after repeated subculture as in the original culture (Marchoux, Landsteiner, and Berliner); this parasite required intact blood corpuscles for its growth.

But in other instances, e.g., foot-and-mouth disease, attempts at cultivation had failed. Immune sera could be obtained by inoculation with large amounts of cell-free infective material—e.g., cow-pox lymph. In conclusion, Prof. Loeffler urged that in view of the great importance of filter passers in the etiology of disease, laboratories should be devoted to the study in all countries.

Sir JOHN M'FADYEAN (London) said that the demonstration of invisible viruses marked a new epoch. The invisibility of a virus was of more interest than the fact that it was a filter passer. The term "filter passer" was not a precise one. Whether bacteria could pass through a filter or not depended on (a) the texture and thickness of the filter wall; (b) the pressure under which the filtration was carried out; (c) the duration of the filtration; (d) the composition of the liquid in which the bacteria were suspended; and (e) the form and dimensions of the bacteria. By way of control it was necessary to show that a small but visible organism in the fluid was held back by the filter while the virus passed through. In the case of human diseases it might be difficult to prove the presence of the virus unless a susceptible animal could be found. In regard to the reproduction of the natural disease by inoculation there were pitfalls. Thus, in the case of swine fever cultures of a bacillus, which was at one time thought to be the cause of the disease, produced the characteristic lesions on inoculation, but the experimental disease was not contagious. On the other hand, the inoculation of the filtered virus of infective pleuro-pneumonia practically never gave rise to the lung lesions characteristic of the natural disease, and the experimental disease was non-contagious; but the same held good of inoculation with the unfiltered infective material. It was a striking fact that the great majority of the filter passers had not been obtained in artificial culture. This might be due in some cases to their being of protozoal nature—e.g., the viruses which were transmitted by insects, such as yellow fever. Again, the occurrence in certain instances of infection by the mouth pointed to the bacterial nature of the parasite. The occurrence of saprophytic invisible filter passers had not yet been demonstrated, but this might be due to ignorance of the conditions necessary for growth. It was probable that great advances would be made in the cultivation of invisible organisms, and he agreed with Prof. Loeffler that the study of this group should be subsidised.

Dr. W. FORNET (Berlin) reported that he had effected the pure culture of the vaccinia virus. The vaccine lymph was sterilised by the addition of ether, which had the advantage of killing off associated organisms and at the same time of not harming the specific agent; the ether could be readily removed by evaporation and its action thus stopped. The lymph which had been so treated remained active after incubation for months at 37° C., and was therefore suited for use in the tropics. Unlimited growth occurred in culture media without any visible alteration, and the infective dose after repeated subculture precluded the idea that proliferation of the virus had failed to take place. Certain microscopic appearances in the cultures after staining by Loeffler's method were described as characteristic.

Prof. KRAUS (Vienna) described experiments with the filtrable virus of fowl plague. His work emphasised the importance of testing various species of animals and of the same species at different ages. Also differences in various strains of the same virus were brought out. A certain virus isolated from a case of fowl plague was found to be infective for both young and old geese when inoculated intramuscularly, whereas the "laboratory" strain of virus failed to infect old geese, which, however, succumbed to intracerebral infection. The serum of old geese vaccinated with the avirulent strain had a prophylactic action against inoculation with the virulent virus. No growth was obtained in artificial media.

Dr. LAMBERT, along with Dr. Steinhardt (Columbia University), had cultivated with success the vaccinia virus in rabbit's cornea along with blood plasma *in vitro*. They employed vaccine lymph freed from glycerine by dialysis, and obtained a number of cultures without the presence of bacteria. The material used for cultiva-

tion was capable of producing only a small number of pustules on inoculation, but after growth for 18 days the culture gave rise to a confluent eruption. They concluded that multiplication of the virus had occurred along with the living growing corneal epithelium.

Prof. G. SIMS WOODHEAD (Cambridge) had failed to obtain positive results on inoculation with filtered vaccine lymph.

Prof. C. J. MARTIN (London) described experiments conducted by Dr. Todd, of Cairo, on the virus of rinderpest, which showed that the causal agent of this disease did not pass through a Berkefeld filter. Starting with infective citrated blood which was active in a dose of 0.001 c.c., and subjecting this to centrifugalisation, the following results were obtained: the top layer was non-infective, the layer of red corpuscles contained the infective agent in only a hundredth of the concentration of the original whole blood, and the greatest part of the virus resided in the leucocyte layer. This appeared to suggest that the infective agent might be situated within cells.

Dr. ALAN B. GREEN (London) had compressed the contents of vaccinia exudates into citrate solution, and so obtained a clear fluid which could be readily filtered. Every filtrate failed to give positive results on inoculation.

Prof. LOEFFLER, in concluding the discussion, said that in many cases there was a justifiable doubt as to the authentic character of alleged filter-passing viruses. Negative results had been obtained with trachoma. Præschner, who had failed to pass the virus of rabies through filters, found that bacilli could be demonstrated in the infected tissues by means of an alkaline solution of methylene-agar. No generalisation of the facts of one disease could be applied to another.—*The Lancet*.

ROYAL SANITARY INSTITUTE CONGRESS.

CONFERENCE OF VETERINARY INSPECTORS.

BOVINE TUBERCULOSIS: ITS DIAGNOSIS. By W. P. STABLEFORTH, F.R.C.V.S.

Mr. President and Gentlemen,—In acceding to the request of the local secretary of the Veterinary Conference of this Congress that I would write a short paper for discussion, I agreed, not that I had much original matter to bring to your notice, but rather to re-introduce an important subject for debate, one which we all know something about, and one that in view of the present legislation, would lend itself to a useful discussion. I propose to treat this subject as a veterinary inspector rather than a pathologist, with a view of arriving at a fairly correct diagnosis of the disease in life.

CLINICAL APPEARANCES.

The clinical appearances are exceedingly variable, depending on the progress of the disease, the lesions, and their situation. Symptoms may be entirely absent in the early stage, and the writer has often found the most healthy to external appearances a member of the group which had reacted to the tuberculin test.

Generally speaking, the advanced tuberculous cow is unthrifty, the skin tight and adherent to the subjacent tissues, emaciated more or less, and often changes colour, becoming lighter in shade; the author has noticed this particularly in red cattle. Edema of the intermaxillary space may be present, and enlargement of the glandular system; this is often pronounced in the region of the tongue, throat, neck, and when so, the patient often makes a variable noise, according to the glands involved, and the degree of interference of respiration. The glands principally attacked in this region are the parotid, sublingual, sub-maxillary, and

post-pharyngeal. The animal may salivate and show difficulty in deglutition if there is any ulceration of the mucous membrane of the tongue or pharynx, or protrude nose and make a decided noise during respiration should the ulceration be in the larynx. If the lesions are confined to the glandular structures, the patient may only suffer inconvenience when feeding or during exertion.

In East Devon, where actinomycosis is very prevalent, the writer has found a very large percentage of these enlargements to be due to the actinomycetes. One must also be guarded when dealing with fat cattle and pedigree stock which has been forced from birth; there is frequently an excessive accumulation of adipose tissue about the neck and throat, and when feeding or exerted, noisy breathing is often heard. In tubercular lesions of the throat, the subject may cough frequently, much louder and more pronounced than when arising from the chest; the slightest irritation is sufficient to excite an attack. When the disease is located in the lungs the cough is soft, muffled, deep, and if accompanied with pleurisy the cough causing pain is short, suppressed, and produced with a careful movement of the abdominal muscles and practically a fixed thoracic wall. The cough may be paroxysmal, easily excited by pressure on the trachea, sudden atmospheric changes, and exertion; in fact a tuberculous cow, unless in the very early stages, cannot stand exertion, and will be found lagging behind her fellows. Frequent coughing without any decided cause ought to arouse suspicion.

The conformation of the chest wall, and the spareness of the ribs in most tuberculous cows lend themselves to aid diagnosis. The contents of the thorax are involved in about 90 per cent. of cases. The respiration may be accelerated, showing towards the end of the expiratory movement a secondary effort, similar to an animal affected with emphysema. Auscultation of the thorax in advanced tubercle, either with the stethoscope or unaided ear, reveals nearly every variety of sound, and this is easily understood when one remembers the great variation of the lesions which may be present, tuberculosis of the bronchi, lungs, pleura, pericardium, heart, with compensatory emphysema, adhesions, deposits, consolidated caseous patches, and enormously enlarged lymphatic glands.

Pulmonary tuberculosis should always be suspected when one finds a frequent cough, nasal discharge with emaciation, and if on auscultation the respiration is rough, inspiration rasping, expiration prolonged, blowing; with absence of vesicular murmur, and should snoring sibilant *râles* or cavernous *souffles* be detected, the inspector may be pretty certain from a clinical examination that he is dealing with tuberculosis.

In the early stages of tubercle of the respiratory tract there is little expectoration or nasal discharge, but later this is considerable. The expectorate is viscid, inodorous, greyish, occasionally offensive, containing pus, and yellowish grey caseous flakes. The symptoms of tuberculosis vary so much, depending on the organ attacked, that it is difficult to lay down any fixed routine for diagnosis, save that the examiner should remember that by far the greater number will be found in dairy stock, and the older the animal the more likely it is to have contracted the disease.

The general appearance must be taken into consideration—unthrifty conditions, tightness of the skin, dry staring coat, accelerated respiration, nasal discharge, cough, intermittent or persistent diarrhoea with tympany particularly if commencing with a newly calved animal, are all suggestive, and perhaps one of the most important symptoms during life is the enlargement of the superficial lymphatic glands, for the lymph glands are the most common seats of the disease. The glands which may be examined during life are the sub-maxillary, sub-lingual, parotid, prescapular, prepectoral,

precurral, tracheal, and cervical (if decidedly enlarged), mammary or superficial inguinal. Those at each side of the trachea at entrance to throat, between the two first ribs, can often be felt on palpation.

Tubercular Mastitis.—Tuberculosis of the udder is a chronic lesion, seldom a primary one—usually a secondary infection from the abdominal cavity—or it may be a generalised lesion; the entire gland is occasionally affected, but it is usually one quarter, perhaps the posterior quarters are most often involved; the gland slowly increases in volume by a progressive chronic interstitial hypertrophy of the connective tissue. At first a small hard non-inflammatory growth can be detected; this often escapes notice, as the character of the milk for some considerable time remains unaltered. It is remarkable how quickly the growth proliferates, until the whole secreting tissue is replaced by a hard fibrous mass, which has been described by many as of wooden hardness. The patient evinces little or no pain on pressure, and the milk remains normal for some considerable time; this fact accompanied by the fibrous non-inflammatory condition of the quarter assists diagnosis considerably. The growth commences usually at the upper part of the gland, the milk gradually becomes less in quantity, thin, bluish, mixed with coagula, and later the secretions may be of a yellowish colour containing flakes. It is not often purulent as in acute or catarrhal mammitis. Rarely caseous centres break and discharge on the surface, the pus containing deep yellow particles of caseous material. The enlargement of the quarter is permanent, and is not followed by atrophy as in most other affections of the udder. The writer does not believe it possible to find tubercle bacilli in the milk unless there is a tuberculous lesion in the gland. A great number of competent authorities think otherwise, but surely it is because at certain stages the lesions are so minute as to escape both macroscopic and microscopic observation.

[The essayist then reviewed the methods of microscopic examination, tuberculin and inoculation tests, and concluded that section with the following extract].

The microscopic appearance of a tubercle, according to Stockman, is as follows: In the earlier stages the tubercles consist of a few large epithelioid cells, which have come from the fixed tissues, and a few leucocytes can be found; the bacilli may be so few as to escape notice. About the tenth day large multinucleated cells appear, known as giant cells; these have a homogeneous yellowish-looking centre with several nuclei towards the periphery.

Older tubercles show giant cells to be more numerous, yellow, structureless, caseous patches are to be seen, fibrous tissue will be seen at their margin, and some encapsulated and showing infiltration with salts. The bacilli will be seen, after suitable staining, between the cells and inside the giant cells. Many of the nodules will have undergone caseous necrosis, and have lost the above appearance.

Giant cells are found in lesions due to other organisms than the tubercle bacilli, such as actinomycosis, chronic interstitial mammitis. The presence of a lesion showing giant cells and acid-fast bacilli (staining after Ziehl Neelson) is diagnostic of tubercle.

DISEASES SIMULATING TUBERCULOSIS.

The diseases which may be confounded with tuberculosis are Actinomycosis, Johne's disease, and Parasitic gastro-enteritis.

Actinomycosis.—This malady is one which may easily be mistaken for tubercle from a clinical examination. One of its most common seats is the throat and tongue and its glandular structures. It is also met with in the udder, and cases are on record where the lesions of tubercle and actinomycosis have been growing side by side. Like tuberculosis, the parasite excites a fibrous prolifer-

ation, which causes hypertrophy and permanent hardness. At the onset the nodules are more discrete than those of tuberculosis, but later become confluent, and at this stage it simulates tubercle. Actinomycosis has a greater tendency to suppurate and discharge. In the udder the growth is usually at the base of the quarter which points to infection by way of the teat. (Stockman).

To establish a diagnosis it is necessary to resort to the microscope. The parasite is seen in animals in colonies known as the ray fungus; they can be seen without any previous staining; also stain well by Plants and Gram's method, although the appearance in the discharge of small yellow or colourless grains, frequently cretaceous, are characteristic of actinomycosis.

In the absence of material for microscopic examination, the writer places the patient on the iodine treatment and has found that if the enlarged glands are due to the actinomycetes or discomycetes, there is a rapid diminishing of the growth as soon as the patient is saturated with iodine. A positive reaction to tuberculin does not prove otherwise, for the reaction may be due to tubercle located in some internal organ.

Johne's Disease.—This is another of the diseases closely allied to tuberculosis, and the writer has not the slightest hesitation in saying that in years past it was the rule to attribute at least 90 per cent. of the cases of chronic diarrhoea to infection of the intestinal tract with tubercle bacilli. It is extremely difficult to differentiate clinically tuberculosis from Johne's disease, and this must be done by eliminating the presence of any other disease.

Intestinal tuberculosis is characterised by intermittent or persistent diarrhoea, with the presence of tympanites after food. The appetite is capricious, and one will most probably find the superficial glands enlarged or other evidence of tuberculosis.

In Johne's disease the patient feeds normally, the appetite is good, rumination continues, and an infected animal will feed up to the finish, the character of the diarrhoea is most offensive, and tympany is hardly ever present. The tuberculin test will not always differentiate, although it will in the majority of cases.

A few weeks ago the writer recommended the destruction of a Jersey cow with emaciation, chronic diarrhoea of eighteen months standing; she was classified as tuberculous. Failing to react to tuberculin, the diagnosis was altered to Johne's disease. On post-mortem the cow was found to have generalised tuberculosis. An animal affected with Johne's disease will react to avian tuberculin, but not to bovine tuberculin; but we have not yet had sufficient experience of this test to fix its value.

It is more than probable that ere long we will have a diagnostic vaccine prepared from cultures of Johne's bacillus, as reliable for testing cattle for Johne's disease as tuberculin is for tuberculosis.

Parasitic Gastro-Enteritis. A disease characterised by a chronic fetid diarrhoea, rapid wasting, anæmia, and œdema, occurring in young cattle from six months to three years old, and occasionally in older animals. It may also be accompanied by parasitic bronchitis; microscopic examination (with low power) of faeces will readily reveal ova and embryos of strongyles. The most common parasites causing this malady are *S. contortus*, *S. flicollis*, *S. gracilis*, etc. The disease resembles both Johne's disease and tuberculosis of the gastro-intestinal tract.

The writer has found the malady curable in a large number of cases by the administration of chlorodyne with lysol or coal-tar creasote.

The PRESIDENT said the stock owner and the authority would be largely affected by the correct or incorrect diagnosis of the veterinary inspector. There were points in the paper which would bear further

elucidation, and he hoped they would have a good discussion.

Mr. BOND (Plymouth) said he had been asked to open the discussion on the valuable paper they had just heard read, but he was somewhat taken aback, because he said this question had within the last 35 years come quite to the front, and they found the word "Tuberculosis" slipping off their tongues, much as the word "Mesopotamia" did from the tongue of the old lady who used to be so fond of reading the Bible. (Laughter). The first recollection he had of tuberculosis was in an article which was published in the old *Veterinary Journal*, which was then edited by John Gamgee. It was there called "Sandy lungs." To-day, however, everybody had got hold of the word "Tuberculosis." They had found that young cattle were exempt from its ravages. Tuberculosis was a question of housing. Wild cattle did not get it until they were put into captivity. The reader of the paper had said that the tuberculin test was to be relied on; but it was not considered so. They were not justified in saying that if they applied the tuberculin test and there was no reaction, that the bullock was absolutely free from tuberculosis. The search for the bacillus was very difficult, but one of the highest authorities had stated that the test for it was easier than the final test for anthrax. They had as fine a means of getting at the facts as they ever would. He did not see the necessity for a full time man being appointed. He could do the work as well as a full time man. If he were called in and asked his opinion by the local authority, they wanted to know whether an animal was tuberculous or not. It was the business of the veterinary surgeon to find out whether the animal was right or wrong, and they must be men enough to back up their opinion before they gave the certificate, and not after. (Hear, hear). It used to be considered a great proof if the animals were wasters, but that was quite a distinct disease and easily noticed, and did not apply to tuberculous animals.

Dr. H. G. GAMLEN (West Hartlepool) said, from the experience he had had of treating human beings for tuberculosis, there was no doubt that the tuberculin test was most reliable with regard to cattle, but he could not agree with some remarks that he had heard there with regard to the tubercle bacilli. He tested thirty milks last week, and he found the tubercle bacilli in nine of them. Therefore he could not see the difficulty that some of them had found. He did it by the ordinary means that they used with regard to sputum. He also used the anti-formaline method. The same result could not have been got by ordinary methods of detection. He used the electric centrifuge, and examined 93 cells, three from each milk.

The PRESIDENT said nineteen or twenty yielded no bacilli. They also gathered that it was not at all sure whether these twenty samples were affected or not, but that Dr. Gamlen did not discover that they were. They must not expect to have perfection. If they did, they would surely stop in their work; if they could not give a counsel of perfection they must allow a little elasticity on the other side. He was very pleased to hear that remarks had been made of this character.

Mr. J. A. DIXON (Leeds), remarked that the question of bacteriological examination of milk samples was now of extreme importance to veterinary inspectors, and he did not think they could collect information on a more valuable or more important point. He had had some experience as an amateur bacteriologist. He had tested many samples with the view of finding the tubercle bacilli, but try as he would he had failed to find it. He was sure the microscope was not at fault. He was quite certain that, as Dr. Savage had said, with the most efficient operations and the best apparatus, mistakes would be made sometimes and cases would be missed; they had an opportunity to try this in every

day work under the Tuberculosis Order. He had known cows which had presented unmistakable evidence of tuberculosis of the udder to be examined by veterinary inspectors under the Tuberculosis Order; and, not satisfied with the clinical appearance, they had obtained samples of the milk of the cow and disregarded the clinical evidence. He thought that that was wrong. If they found the bacillus in the milk it strengthened them, but if they did not find it they should be quite content to go on without it. They should not regard the milk examination as superior to the clinical examination. The collecting of the samples was important and must be carried out by the inspector himself and under proper precautions. They would get a variety of microscopic organisms, the one-twelfth lense was quite a good one, but it was necessary to have a mechanical stage. He was surprised to hear Mr. Bond say that animals affected with tuberculosis did not become wasters. It had been his (the speaker's) short experience that wasters was an outstanding feature of old cases of tuberculosis. In the first month of the operation of the Order they slaughtered thirteen cows in his district and twelve of these were wasters. He thought one was slaughtered because she had tuberculosis of the udder. There was considerable danger in the diagnosis, as he had found in one or two cases. The tuberculin test was of the greatest value, and that was why he took up what some people regarded as a strong and arbitrary position with regard to agriculturists. Believing in the tuberculin test so thoroughly, he thought the farmer could, if he liked, obtain this test for every cow. A man could depend upon keeping his cows free from tuberculosis, and it was only a matter of carelessness and indifference that he did not do so. He (the speaker) had the utmost confidence in the tuberculin test. Quite recently he had noticed in some professional circles that there was a tendency to question the reliability of the tuberculin test. He thought the day had passed when veterinary inspectors ceased to believe in the tuberculin test. (Hear, hear). The duties of our veterinary inspectors were most exacting, and the tuberculin test when properly applied was well worth while.

Mr. MALE thought they ought to discuss this matter thoroughly before passing on to another subject. There was one point which Mr. Stableforth made which he (the speaker) took exception to. Mr. Stableforth said that veterinary surgeons were not qualified for bacteriological work, and implied that they were not able to carry this out. That was hardly stating the facts. As Mr. Stableforth showed, he was a bacteriologist. Any one reading his paper could see that he was perfectly able to examine. Many other veterinary surgeons in the room were competent to carry on bacteriological work under this Order. (Hear, hear). Some had gone to the trouble of taking a bacteriological course under experts, and they had taken every means to rub up their knowledge on this subject. He did not think, therefore, that Mr. Stableforth's statement was a correct one. He (the speaker) was also glad to hear the reliability of the tuberculin test taken up. In certain quarters the tuberculin test was rather taken exception to. There was one point which he thought they should insist on, that tuberculin must not be allowed to be used by veterinary chemists, farmers, and other people, and so destroy the utility of the test. (Hear, hear). In his own district veterinary chemists had gone round testing the cows as soon as the Order came in, at ridiculously low fees. Let them have tuberculin from the Pasteur Institute, or from the Royal Veterinary College, or wherever they liked, but they should see that it was not sold to those not qualified to use it.

Dr. H. KERR (Newcastle-on-Tyne) said he thought that in the memorandum that accompanied the Tuberculosis Order of 1913, the direction to examine the milk

microscopically emanated from the Medical Officer of Manchester, but he did not say that this microscopic examination should be the final examination. As to the practicability of clearing herds of tuberculosis, that was a point of which they were rather proud in Newcastle. In two or three large dairies the tuberculin test had been of the greatest assistance in keeping the tubercle from the milk, and in one or two of the large dairies they had a tuberculin milk test, which was used by the dairy people, and they sold their milk at market prices. During the present year, speaking off-hand, they had taken samples haphazard in the market for examination for tubercle bacilli, and from one big dairy they secured quite a number of tuberculous samples. In another big dairy, which had a very wide source of supply, they guaranteed the tuberculin test, and in that case the authorities had not one sample containing the tubercle out of the large number examined. The examination for the bacillus of tuberculosis was done at Newcastle by our eminent bacteriologist.

Dr. J. H. GARRATT (Cheltenham) said in his opinion the examination must be done by an expert to be reliable, otherwise the results were worse than useless. (Hear, hear).

Mr. R. GLOVER (West Ham) remarked that he wanted to get information, if possible, as to how local authorities were relying on bacterial examination locally, or how far they were consulting institutes where experienced, trained men were engaged.

The PRESIDENT replied that to a Congress of veterinary inspectors that was of extreme importance. It had been very commonly expressed that day that an expert should be called upon to examine the milk. The first question that came to his mind there was, what was an expert in the examination of milk for tubercle bacilli? That he was afraid, they could not define there, because they had no means of doing so. But as an individual who was engaged in the microscopic examination of pathological problems before many of those who were "expert" at the present day had much knowledge of any professional matters at all, he could not conceive what an expert was if he was not a veterinary surgeon, who had been educated in pathological processes, had had two years in a laboratory, and had rubbed up his knowledge afterwards in a special course. What expert knowledge did they require other than this to render a man capable of examining for tubercle bacilli in milk? (Hear, hear). Prof. Delépine, whose expert knowledge nobody could possibly question, nor the breadth of view with which he always faced such matters, had said that the properly qualified veterinary inspector had the power of picking out infected cows and notifying certain dairies as harbouring the tubercle bacilli. They could go to the dairy, pick out the cow, remove her, and insure that the supply of milk was free from infection.

Mr. J. A. DIXSON (Leeds): That is so.

The President said that was all they wanted (Hear, hear). The veterinary surgeon was quite capable of examining for tubercle bacilli and rendering that milk supply perfectly safe; and what was worse, he attributed to him the power to diagnose tuberculosis by the ordinary means of observation. He valued most highly the application of the tuberculin test if it was carried out in a proper manner. But even the value of a tuberculin test would depend very largely on the individual who carried it out. There was no question about that (Hear, hear). He thought himself that really they had the machinery that was capable of rendering milk practically free from the tubercle bacilli which emanated from the bovine. Whether legislation on the point was sufficient to make that applicable was another matter.

Mr. STABLEFORTH, in reply to Mr. Bond and the tuberculin test he was surprised to hear him say that it was unreliable. The only unsatisfactory thing about it was that in an advanced case it sometimes needed con-

firmation by the biological test. With regard to Dr. Gamlen and the milk mistakes, he thought Dr. Gamlen said he had examined thirty cases, with positive results in nine. He (the speaker) asked what other tests were applied to the remainder of the milk. Had the others been subjected to a biological test, he would have found how they stood.

Dr. GAMLEN said a large proportion of the others would have tuberculin.

Mr. STABLEFORTH said he was afraid Mr. Male had misunderstood him in regard to a veterinary surgeon not being equipped. He (the speaker) did not say that they were not capable of making a bacteriological examination of milk, but he did say that in a difficult case they were handicapped in giving a correct diagnosis. He was acting for the Devon County Council, and part of his instruction was not to apply the tuberculin test more than was necessary.

VICTORIA VETERINARY BENEVOLENT FUND.

The quarterly meeting of the Council of this Fund was held at 10 Red Lion Square, London, on Thursday, July 3rd. There were present Messrs. Dunstan, Slocock, Sumner, Garnett and Shipley.

The minutes of the previous meeting were read and confirmed.

On the proposition of Mr. S. Wharam, seconded by Mr. Abson, Mr. R. C. Trigger, J.P., was unanimously elected President for the ensuing year.

Messrs. Freeman Barrett, P. J. Simpson, E. A. West, and W. Burt were elected Vice-presidents.

Mr. SHIPLEY was re-elected Secretary and Treasurer on the proposition of Mr. Abson, seconded by Mr. Garnett.

SECRETARY'S REPORT FOR THE QUARTER.

To the Members of the Council of the Victoria Veterinary Benevolent Fund:

The annual meeting of the Society was held at 10 Red Lion Square, London, on Wednesday, June 4th.

First, I think, I should call to your notice the handsome donation of a cheque, value £70, received from Mr. P. J. Simpson, of Maidenhead, the result of his efforts in producing a play for the benefit of our Fund. I have received from him the following letter:—

Maidenhead, May 13th.

Dear Sir,—I have very great pleasure indeed in enclosing you a cheque for seventy pounds as a donation to the Victoria Veterinary Benevolent Fund.

This amount represents the profit on the performances of "Sweet Lavender," and the generous result of my appeal to my clients and friends for donations to the Fund. I enclose you a short balance-sheet showing how the amount is arrived at.

I leave the disposal of the amount to the discretion of the Council of the Fund, but I throw out the suggestion that if sufficient money can be obtained to add to it, and ensure a place for a boy or girl in some institution, that is what I should like to see it used for, but this is only a suggestion.—Faithfully yours,

P. J. SIMPSON, (Signature), F.R.C.V.S.

We owe a debt of gratitude to Mr. Simpson for the work he has done for us, and can only hope that this will be emulated by other members of the Council. I shall be glad of your instructions as to the disposal of this sum which I have temporarily placed on deposit.

Financial Statement.—We have expended in the half year to June 30th £179 7s. 4d. Our income has been £257 17s. 5d. We have therefore a balance of £81 2s. 1d. Outstanding subscriptions amounted to £60 15s. Dividends £48 3s. 9d., making a total, if all outstanding

subscriptions are paid, of £190 Os. 10d. to meet a liability of £174 for relief. If any fresh cases occur this will leave practically no money to help, and no balance for incidental working expenses.

We have now thirty-two members of the Council. If I could only induce them to find two subscribers each to our Fund how much better off we should be.

We are also greatly indebted to the veterinary press for the help they have given us, and I especially appreciate very much their kind remarks.

I have to report the death of Mrs. Johns, which occurred in Edinburgh in a nursing home. I have received communications from the Secretary of this home referring to the final expenditure for funeral expenses, and would suggest to you that we remit a cheque for two pounds towards these. A sum of three pounds has already been remitted by the National Veterinary Benevolent and Defence Fund towards this object.

I would recommend that the grants to all the old recipients be continued.

Further investigations in the case of Miss Worsley have been made, and on the recommendation of Prof. Dunstan, a cheque for ten pounds was remitted.

Further applications for relief have been received from Mrs. Shivas. On the authority of the Finance Committee a cheque for two pounds was remitted. May I suggest that a grant of 5s. per week be made in this case.

An application from Prof. O'Connor, Secretary of the committee in Ireland, on behalf of Mrs. Margaret Walsh, referred from the last Council meeting, has been considered by the Finance Committee, and an immediate grant of five pounds was made on their recommendation, and I suggest that a further weekly grant of 5s. be made.

I regret that many annual subscriptions are still in arrears, in fact some £60 is required for this quarter. I hope, however, to give them all a reminder in the course of time. I wish I could instil in the minds of those subscribers that the unnecessary expense in postage and literature which is thus entailed materially lessens the amount available in the working of the Fund.

A few new subscribers have been enrolled since the last annual meeting.

List of New Subscribers, from April, 1913.

Bowden, J. Scott, Whitehaven	£1	1	0
Vaisey, T. L., Board of Agriculture	10	6	
Alexander, T. J., Kinsale, Ireland	10	6	
Cundall, F. H. W., Swindon	10	6	
Sewell, A. J., London	5	0	0

Marriott, S. W., R.V.C., London	10	6	
Anderson, W. H., Uxbridge	10	6	
Meadows, D., India	3	0	0

Mr. GARNETT proposed, and Mr. Slocock seconded, that the donation from Mr. Simpson be left on deposit at present with a view to attempt to carry out his wishes.

The SECRETARY pointed out that a sum of £90 would be required to get a child into a charitable institution with a view to education.

Mr. Simpson gave a further cheque of £3 4s. 5d., donations received since the remittance of the last cheque.

On the proposal of Mr. Abson, seconded by Mr. Garnett, a hearty vote of thanks was given to Mr. Simpson for his gift, and the Secretary was instructed to write expressing the Council's gratitude.

Proposed by Mr. Sumner, and seconded by Mr. Burt, a sum of £2 be sent to the Secretary of the Home in Edinburgh towards the cost of the funeral expenses of Mrs. Johns, an old recipient.

The Council confirmed the action of the Finance Committee in making grants to Mrs. Shivas and Mrs. Walsh.

A weekly grant of 5s. each was voted to Mrs. Shivas and Mrs. Walsh, on the proposition of Mr. Burt, and seconded by Mr. Wharam, the finances of the Fund being insufficient to make a larger allowance.

Cost of Tuberculosis Order in Cornwall

At the quarterly meeting of the Finance Committee of the Cornwall County Council, the Chairman said that at the last meeting a considerable sum was provided for the matter of tuberculosis in cattle, and although the Order had been in operation only two months, accounts amounting to £363 12s. had been received by the Contagious Diseases (Animals) Committee. The special point which should be brought to the notice of the Committee was the very heavy charges made by the veterinary surgeons for examining the animals.

The Hon. John Boscawen said a sub-committee had been appointed to consider the whole question, and he thought it would be wise to postpone the payment of the bills until the sub-committee had met.

The Chairman inquired whether the Contagious Diseases Committee had any control over the veterinarians' charges.

It was stated that the Committee could make their own scale of charges, but had not done so, and the Committee had, pending the drawing up of a scale and regulations, provisionally adopted the scale of the National Association of Veterinary Surgeons.

Mr. Hawk asked what had been received in the matter of salvage in the cases of diseased animals, and it was stated that no figures could yet be given, because the amounts had not been received, except from one police district, where the sum was £10.

Mr. Hawk suggested that no provision had been made for salvage. When an animal was not seriously diseased it should be taken to a slaughterhouse. It might be that three-parts of the carcass was fit for human food. Instructions had not been given to take them to a slaughterhouse.

Mr. Liddell (assistant clerk) stated that instructions had been given when the forms were sent out a month or six weeks ago to the police and to every veterinary inspector in the county.

Mr. Boscawen said that in one or two cases the diseased carcasses had been sent to the knacker's yard, and the money was being collected.

The Chairman said it was extremely necessary the Committee should draw up their own scale of salaries. He noticed a charge of two guineas was made for applying the tuberculin test, which meant four visits, but he understood that any intelligent man could take the temperature of a cow and report to the veterinary, and this would save two visits. In all the cases four visits had been charged for at the rate of 10s. a visit. "That," he said, "is rather more than a doctor gets for attending me." (Laughter). They could not dispute the payment of compensation. In every case the animal had been properly valued, and the compensation had to be paid.

Mr. Bain said he believed some of the veterinarians' claims were not in accord with the Veterinary Association's scale, but below it.

The Chairman: The scale in my opinion is too high. Mr. Bain inquired the amount due for compensation, and the amount charged by the veterinary surgeons, and the Chairman replied that the figures were £108 10s. and £206 3s. 6d. respectively. The veterinary surgeons' bills were nearly twice the amount of the compensation.

Mr. Bain asked if one district was not enormously high.

The Chairman replied that it was the Camelford district, a part which one would have been inclined to believe was healthy. The veterinary inspector in that district had a bill for £88 5s.

Mr. Bain: Wasn't it found that a large proportion of the animals were not suffering from tuberculosis at all?

The reply by the Chairman and Mr. Liddell was that it was the other way about. Of a total of 27 in the Camelford district, four only were found not to be diseased. One other died before valuation could be made, and another was slaughtered by the owner before the veterinary surgeon could do anything to it.

Mr. Thomas suggested that, considering the amount the County Council were called upon to pay in the short time the Order had been in operation, it would be proper for the sub-committee to take into consideration the question of the appointment of a whole-time veterinary inspector for the county. (Mr. Boscawen: Hear, hear.)

The Chairman thought the sub-committee should bring up a full report on the whole subject, including the question of a reduced scale of charges on the employment of a whole-time inspector.

Mr. Boscawen said in the scheme he was going to lay before the sub-committee he had thought of having a veterinary inspector for the county, a whole-time officer, who should be under the medical officer of health and attached to the sanitary office, with which department he would be associated when the Milk Bill was passed.—*The Western Morning News*.

Tuberculosis Order, 1913.

PROSECUTION AT HEREFORD.

At the Hereford Police Court, on Thursday, 21st ult., before the Mayor (Mr. H. Walker), Alderman James Corner, Mr. F. H. Merrick, Mr. W. Ashburner, and Mr. C. Hatton, Arthur Allington, farmer, of Barr's Court, was summoned for not reporting two cases of tuberculosis in bovine animals and failing to disinfect his premises on July 25th.

Defendant pleaded ignorance.

Mr. E. A. Caple said the Order came into operation on May 1st, and that was the first prosecution of the kind in the county. The two cows were in a deplorable condition, one in particular, and the animals, on being slaughtered and a post-mortem examination being made, showed definite signs of tuberculosis. He hoped the Bench would inflict such a penalty which would serve as a warning to others.

Albert Coles, a clerk in the Town Clerk's office, produced a pamphlet which had been published and circulated, giving a full text of the Order. No notice was received from defendant of the cases of tuberculosis.

Defendant said he had never seen the pamphlet.

P.C. T. Edwards said he served a copy of the pamphlet at defendant's residence on April 21st, leaving it with Mrs. Allington.

Detective Ovens said that on the 24th ult., in company with Detective Hoskins, he was in the neighbourhood of defendant's farm, and saw a little red cow in the meadow, which was in a very poor condition. He noticed a brindle cow, a little red Hereford, and a Short-horn, which appeared very thin. It appeared to him to be tuberculosis. He reported the matter to the Chief Constable, and acting on his instructions called in Mr. Barling, veterinary surgeon, to examine the cattle. He accompanied Mr. Barling to the farm on July 25th, and in a stable adjoining the house he saw a cow in an ex-

remely poor condition. Mr. Allington was away, but he saw him the following day, and accompanied him to Mr. Barling's. Mr. Barling told defendant in his presence that two of the cows would have to be destroyed, as they were in an advanced stage of tuberculosis. No notice had been received of the disease.

Mr. James Barling, M.R.C.V.S., said he visited defendant's premises with the Chief Constable and Mr. Ovens. They found a red and white cow in a stable adjoining the house, and he did not think he ever saw an animal so poor and emaciated in his life. It was suffering from tuberculosis in an advanced stage, and must have been suffering for months.

Alderman Corner: Was the condition such that it must have attracted the attention of persons seeing the cow?

Witness: Undoubtedly. Continuing, witness said that they saw in a meadow 31 cows and a calf, and three of the cows were looking suspicious, and he had to report them under the Tuberculosis Order; a brindle cow in particular, with calf.

Defendant: I am not summoned for that.

Witness: No, but I am bound to refer to them in my report. Witness said they then found in another building a red cow with a white face in a semi-conscious state, and undoubtedly suffering from tuberculosis. He saw defendant on the 26th (the day following) and told him the cows would have to be destroyed. They agreed as to the price to be paid under the Order. If a cow was tuberculous, 30s. was paid, less expenses.

Alderman Corner: The net result is that the owner of the cattle gets practically nothing.

Defendant: Not a penny-piece.

Mr. Sidney Protheroe, sanitary inspector, said he had received no intimation from the defendant of the disease.

Alderman Corner (to Mr. Barling): What is the effect upon the other cattle where tuberculous cattle are allowed to move amongst them?

Mr. Barling: It is undoubtedly contagious, not only to the other cattle, but to children. It is absolutely dangerous.

Defendant, on oath, said one of the cows had had a calf, and he thought its condition was attributable to that fact. He added; "I certainly don't say they were all right, because I don't think they were, but I did not think they were tuberculous. It is a very deceptive disease."

Alderman Corner: But they actually attracted the attention of the police officer.

The summons for failing to disinfect was then proceeded with.

Defendant said he did what was required. He had not seen the Order.

Detective Ovens said that disinfection had not been carried out four days after the notice to do so had been served upon defendant. The cleansing was not carried out until ten days had elapsed.

Mr. Barling said the condition of the buildings was very bad.

Mr. Protheroe, recalled, said he had not visited the premises since defendant gave up providing milk, some two years ago. He devoted his attention mainly to dairy farms, and this was a stock farm.

The Bench retired, and after a lengthy consultation, the Mayor announced that they found the cases proved. As this was the first prosecution of the kind they had decided not to take such a serious view of the matter as they otherwise would have done. In the first case, defendant would pay £5 in respect of each cow, and £2 4s. 6d. costs, and in the second case he would be fined £1 and £1 0s. 6d. costs, a total of £14 5s.—*The Hereford Journal*.

* As Diseased or Exposed to Infection

Electrical Sterilisation of Milk.

At the English-speaking Conference on Infant Mortality, held at Westminster, Dr. E. W. Hope, medical officer of health for Liverpool, mentioned that a large number of careful experiments had been made during the last two years with the view, if possible, of lessening the cost of sterilisation, and careful researches had been carried out at the University of Liverpool by Professor Beattie and others in regard to the electrical sterilisation of milk in flow. The upshot of these investigations showed that by electrical methods, milk could be effectually sterilised, all extraneous organisms being destroyed. No change whatever took place in the milk; the flavour, taste, chemical composition, and so forth being absolutely the same as in pure, fresh milk. The process was very much cheaper than the ordinary Pasteurisation by heat. Various pathogenic organisms had been experimented upon, with perfectly satisfactory results. The Corporation had authorised the installation of a plant at one of their depots for this process, which had now quite passed any experimental stage, and which had, he believed, a very valuable future before it.—*Farm and Home.*

The New Forest Ponies.

Two years ago the Burley Association of owners and breeders of New Forest ponies decided to try the experiment of offering a limited number of premiums for mares and fillies turned out in the forest which had never been hand fed. These ponies are practically wild, gaining their own living in the forest. In secluded

haunts the foals are born and remain with their dams, dependent on them for their food. Of these foals a certain number are taken up and sold as suckers every year, but others are never handled at all, and are left out till they in their turn develop into brood mares and stallions. For two years past the Burley Association has directed its attention to these forest-haunting mares, distributing premiums in such a way as to encourage the owners, many of whom are small holders and working men, to retain the most likely mares for purposes of breeding. It is these non-hand-fed ponies which are the backbone, both physically and commercially, of the forest breeds of ponies. For, as one of the most experienced of forest pony men, Mr. Charles Evemy, now the senior agister, remarked to me, "As soon as you begin to feed your ponies the profit vanishes."

But this is not the only reason for encouraging these wild creatures, for after a week spent in most careful examination in all parts of the forest, the judges found that the ponies which were the best shaped, the finest movers, and by far the best in condition, were those which gained their own living on the forest without assistance. One of the oldest owners explained the reason of this. The most valuable quality of a forest mare is self-reliance and resourcefulness, and this, it appears, is easily lost if an owner, thinking to improve their condition, once begins to feed them, for the animals soon lose their will and desire to shift for themselves. They go back, it is true, into the forest when their ration is consumed, but cease to range widely and search closely for the varieties of food which the forest affords to their wilder sisters. They crop listlessly here and there, never wandering far from the homesteads, and they spend much of their time crouching in the

shelter of bushes. They lose condition, and can be easily distinguished from the true wild ponies by their poverty of appearance, their unthrifty coats, and their too often misshapen forms.

The wild pony ranging over many miles in search of food exercises herself and her foal, hardens the bone, develops muscle, and actually puts on flesh. It is in these bolder spirits that one sees the remarkable action characteristic of the true forester. The best have a free, level action, use their shoulders, flex the hocks in a delightful manner, and trot or gallop smoothly over the roughest ground without a false step or a mistake. Nothing stops these ponies, and I saw four in succession which were being gently moved for my inspection trot quietly up to a stream with a bad take off and a boggy landing, and each in turn cleared some 6ft. without hesitation and perfect ease.—*Field*.

The Traffic in Old Horses.

The Board of Agriculture issued on Monday, Aug. 25, the annual report for 1912, of proceedings under the Diseases of Animals Acts and the Markets and Fairs (Weighing of Cattle) Acts [Cd. 6737].

The Assistant Secretary, Animals Division, Mr. A. W. Anstruther, states that the shipment of old horses to the Continent is now carried on under greatly improved conditions, and that in view of the exceptionally heavy storms in the last quarter of the year, the percentage of losses must be regarded as very small. From Jan. 1 to December 22, 15,734 horses and one donkey were shipped from English ports to Rotterdam; no complaint was received from the Dutch authorities as to their condition. The total number of horses shipped to Antwerp during the year was 17027 and 16,988 arrived without injury. The others died on the voyage. The number exported to Ghent from Great Britain and Ireland was 8,265, viz., from London 5,399 horses, two mules, and four donkeys; from Hull 1,788 horses; and from Goole 1,078 horses. Of these 1961 were working horses and described as carriage horses, hacks, hunters, and troop-horses, 1725 were five years of age and under, 236 horses over six years of age were tested with mallein, and 5304 were slaughtered for food, principally for sausages. The casualty returns were under one per cent.: 5,891 horses were exported to Amsterdam and, notwithstanding the exceptionally heavy storms during October, November, and December, the animals arrived in good condition and the injuries reported were only 31 for the year. The deaths numbered 84.

The veterinary inspector who in the course of his duties visits railway stations in connection with the conveyance, watering, and feeding of horses in transit reports that, in consequence mainly of the action of the inspectors of the Society for the prevention of Cruelty to Animals, the various railway companies concerned have now decided to take concerted action in this matter. Arrangements have been made by which all live stock will be fed and watered, and special labels will be attached by the railway officials to each truck, showing when and where the animals were last fed and watered, and the officials at all stations have instructions to examine trucks containing live stock on arrival. He reports also a great improvement in the condition of the trucks used for the conveyance of animals, owing to the supervision exercised by the officers of the local authorities.

The report also gives a detailed history of the outbreaks of foot-and-mouth disease in Great Britain in 1912. The disease was detected in 16 counties—15 in England and one in Wales. The animals attacked were 512 cattle, 40 sheep, and 93 swine; and the animals slaughtered as diseased or as having been exposed to

infection were 3,084 cattle, 6,410 sheep, 890 swine, and five goats.

In 1912 1,756,277 dog licences and licences for hounds were issued in England and Wales, and 126,728 in Scotland. These figures show an increase of 50,394 in England and Wales, and 5,770 in Scotland as compared with 1911.

Hydroquinine Hydrochloride.*

A quinine substitute of synthetic preparation has been placed on the market. It differs from quinine by the addition of two more atoms of hydrogen per molecule, and is in the form of white crystals of very bitter taste, very easily soluble in water and also in alcohol, but insoluble in ether. The toxicity of this alkaloid is about the same as that of quinine, if anything slightly less. As an antimalarial specific it is said to be superior to quinine hydrochloride, and possess as well the great advantage of much higher solubility. A future is also anticipated for hydroquinine as a trypanocidal drug, both in animals and in mankind. Intravenous and intramuscular administration is much more conveniently carried out than with quinine salts, owing to the solubility and consequent small bulk of a given dose. Lenzmann has, it appears, been treating whooping-cough with this new drug, injected intramuscularly, with excellent results.

(Vereinigte Chininfabriken Zimmer und Co., Frankfurt. London Agents: Widenmann, Brocher and Co., 1 Fenchurch Avenue, E.C.)

Tuberculous Poultry.

Relative to the inspection of the food supplies at Smithfield, the last report of Dr. W. Collingridge, issued in his capacity as Medical Officer of Health, contains the following statement:—

"Attention is being directed to the prevalence of the disease in poultry by making a post-mortem examination of emaciated fowls, condemned as unfit for food, in the City Markets. Those examinations are proceeding, and at present it is sufficient to state that 50 per cent. of poor quality fowls are affected with tuberculosis, and in a degree which requires to be seen in order to realise its importance."

Swine Fever Serum.—It is estimated that 6,000,000 pigs were lost through swine fever in the United States last year, and a considerable proportion of that loss, the Department of Agriculture declares, is due to the supply of bad serum for the inoculation of the animals, by private firms whose concoctions are not tested. To prevent this abuse the Department has issued an order placing all makers of swine fever serum under the supervision of the Bureau of Animal Industry. They will have to register under the Bureau, to label their products, and to conform to certain sanitary requirements.

Boy Shot by "Humane Killer."

The accident occurred at Comeragh Mews, West Kensington. A horse which had become unfit for use was despatched in the yard belonging to the Mews, and the bullet passed through the fore portion of the animal's neck and entered the head of a nine-year-old lad who was standing in the road beyond. The boy was taken to the West London Hospital, where a bullet was found in his head, having entered near the right eye. It is feared that he will lose the sight of the eye.

The Handling of Wool.

At the annual meeting of the Royal Agricultural Society at Bristol, Mr. J. W. Elwes suggested that that Society should appoint an expert to advise growers in the handling and disposal of wool. The members of the British Wool Buyers' Association complain, and complain with cause, that many farmers are not so careful in the grading and get up of their wool as they might be. In many cases no attempt is made to classify and render uniform the different classes of clips. In others, brock, clods, vegetable matter, and all kinds of broken and detached portions, which ought to be set aside from the first, are freely rolled up with and included in the major bales without any intimation of the fact being made to the broker. The result is that when the wool reaches the manufacturer it is either in large measure rejected altogether or the broker has to stand in and accept a reduction in price. It is not to be expected that the purchaser will accept a situation of that sort without protest. He simply protects himself the following year, and either refuses to deal with the particular grower altogether, or offers such a reduced price as he fancies will leave ample margin of cover. The Colonial, in this matter, has long since learned his lesson as the result of bitter experience. No small part of the high reputation which colonial and other wools now enjoy on the London and other British markets is due to the fact that it is carefully classed and graded before being baled. The value of British wool is not the insignificant item that is sometimes supposed. At present it is worth about $2\frac{1}{2}$ million pounds per annum, and it is confidently expected that it may become of even greater value in the near future.—*N.B.A.*

Spring in Australia.

August finds the brief, mild Australian winter already breaking, and the countryside alive with the first signs of spring. The natural grasses are moving and making good feed for live stock, although as yet they are far from their best. The farmers of the Commonwealth are welcoming the summer, while they in Britain are making preparations for the long months of winter. The passing from winter to summer in Australia is not as it is here in the north. The native evergreen vegetation prevents those sharp divisions of the seasons familiar to Europe, but still the changes are clearly marked, the leaves do not fall, they take on a livelier green as summer approaches, and shrubs are beautiful and fragrant, with a wealth of blossom. The land, too, becomes a wide garden of wonderful wild flowers. The Australian wild flowers are sometimes charged with being scentless and this is true of some of the most beautiful blooms. But there is compensation in the delightful perfume of the blossom of the wattle and the gum. The gum (eucalyptus) blossom varies in colour according to the species and location; sometimes it is a gorgeous red, sometimes pink or yellow. The Scotsmen and Englishmen in many parts of Australia find the spring almost as pronounced and as stimulating as they do in their native land in the north.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Aug. 26.

REGULAR FORCES. ARMY VETERINARY CORPS.

The following Captains to be Majors, under the provisions of Article 341, Royal Warrant for Pay and Promotion, 1909:—

E. B. Bartlett. Dated May 19.

A. J. Williams, F.R.C.V.S. Dated July 6.

J. J. Griffith, F.R.C.V.S. Dated August 24.

The Price of Army Horses.

The Argentine Rural Society have just published some very interesting figures with reference to horses for the Army. In April last a show of Army remounts was held, at which 577 horses were entered. Of this number 432 were bought for the Army at prices ranging from £26 4s. to £52 8s., and an average from £37 11s. 8d., and practically all the rejected horses were bought by the local municipality. If this can be done in a country where horses are notoriously cheap and cost very little to rear, how is it that in England the War Office cannot give a *paying* price to breeders of this class of horse? W. T. HALL, in *The Live Stock Journal*.

Personal.

Mr. W. F. HOUSTON, M.R.C.V.S., Paisley, acted as judge in the light horse class at the annual show of the Islay, Jura, and Colonsay Agricultural Association at Bridgend, Islay, on Thursday, 14th inst.

Mr. G. PARKER SHORT, M.R.C.V.S., Torquay, has been appointed Honorary Veterinary Surgeon to the Torquay and Devon Canine Association.

OBITUARY

Mr. CHARLES SUTTON, a Peterborough veterinary surgeon, took hydrochloric acid in mistake for spirits of camphor, and died shortly afterwards.

[We do not find this name in recent editions of the Register. It appears that Charles Sutton, M.R.C.V.S., who graduated in 1869, was taken off the Register as deceased in 1909.]

NISBET.—At Boundary House, Fence Houses, on the 26th inst., Ann, wife of J. Brodie Nisbet, F.R.C.V.S.

The death is announced last week of Mr. David Young, the able and widely-known editor of *The North British Agriculturist*, from 1887 to 1911.

"Mr. Young was the son of a farmer, born at his father's farm at Smediton, near Carmyllie, Forfarshire, in 1852. He followed the plough in his early days, and on the death of his father, took over the farm, and, for five years carried it on, completing the then-current lease.

As a journalist, Mr. Young had a retentive memory and a quick, well-informed mind for dealing with facts, and this found expression in a style which was at once outspoken, trenchant, and telling. He dearly loved a controversy, and was in his element when breaking a lance with either friend or foe. Of him it may justly be said, in the poet's words—

"He can distinguish and divide
A hair 'twixt south and south-west side;
On either side he can refute,
Confute, change hands, and still dispute."

He was nevertheless a man with high ideals of truth and justice, and many found in him a warm-hearted and steadfast friend, as well as a pleasant and genial companion."—*N. B. A.*

GOVERNMENT PUBLICATIONS.—Messrs. Wyman and Sons (Ltd.), have published the following, the prices including postage:—Annual Report of Board of Agriculture *re* Diseases of Animals Acts, etc., 1s. 2d.; Return *re* Experiments on Living Animals during 1912, 9d.; Dogs Protection Bill: Report, 2½d.

CORRESPONDENCE.

UNSUSPECTED TUBERCULOSIS.

Sir,

I have read with much interest the note under the above heading which appeared over the name of W. Brown, Workop, in your issue of the 10th inst.

In my limited experience I have also noticed similar phenomena at times; that is to say, that an animal shortly after parturition developed acute tuberculosis; and it is an aspect of the disease that has attracted my attention to a great extent. I would like therefore to ask Mr. Brown if these animals showed any symptoms of tubercular disease before pregnancy?

In his note it is stated that the act of parturition acted as an exciting cause. If I may be allowed to say so, I am rather of opinion that the fact of pregnancy acted as a deterrent to the development of the disease, and that it was the cessation of the pregnant condition which permitted of its growth. This may appear to be a quibble, but in some cases it may be an important quibble, as it undoubtedly is in human medicine.

During a chat with some medico friends I happened to remark that tuberculous people were apparently as fertile as the daughter of Latona, when one man who had a large practice in an industrial district replied, "Yes, and that is not the worst aspect of the case, and tuberculous women realise that pregnancy deters the ravages of disease and therefore strive all they know to get into 'an interesting condition.'" He informed us that in his district he knew at least two cases where women were keeping themselves alive by such means.

Osler says "pregnancy may hold the progress of the disease in abeyance," but asserts that there may be truth in the axiom of Dubois, "If a woman threatened with phtisis marries she may bear the first accouchement well, a second with difficulty, and a third never."

I put forward these few remarks with diffidence in the hope that some of our experienced practitioners may be tempted to write on the matter from their standpoint, and thus raise a point which is not without interest to our stock-breeders.—Yours faithfully,

MOMPARA.

August 27.

MILK FEVER,

Dear Sir,

In your issue for July 19th, 1913, I note "Milk Fever: Suggestions for Prevention," the author, Mr. W. E. Blackwell, M.R.C.V.S., calls attention to the value of leaving a good supply of milk in the udder as a pressure agent. In discussing the probability of the condition being a toxemia, he assumes the possibility of the pressure stopping the entrance of the supposititious toxin into the circulation. Now, assuming the presence of toxins in the blood as the cause of the very grave symptoms exhibited in "milk fever," how can ballooning the udder with air or oxygen, or dilating it with solution of KI, normal saline solution, or even water, exercise any beneficial influence on the condition of the patient? It is not the toxin in the udder, but the toxin that has got out of the udder that kicks up the trouble—if a toxin is the cause of the condition. And to admit that air, oxygen, or medical solutions gain access to the circulation—at least in case of the air or oxygen—is absurd. Furthermore, to believe that blowing up the udder by means of a bicycle pump (a common emergency method in my country) would neutralise a toxin and stop its formation in a comparatively few minutes, leaving the patient not recovering, but to all intents and purposes well, implies credulity. Is it not well to rest on the fact that ballooning the udder is almost a specific treatment, and say that we don't know the cause! Like Mr. Blackwell, I am agnostic in the matter.—Yours truly,

THOMAS B. ROGERS.

Woodbury, New Jersey, U.S.A.

August 14.

Sir,

Regarding Mr. Blackwell's suggestion appearing in the issue of the 19th ult., I have always noted that in districts in Ireland where it was the rule to leave the calf "on the cow" for 24 hours, cases of milk fever were practically unknown; whereas in other localities, where the custom was to remove the offspring at once and feed it from the pail, milk fever was general.

Just now, I have in my mind a practice in Scotland, where latter arrangement was by dairymen strictly adhered to, and the cows never saw their calves; there milk fever cases were of daily occurrence.—Yours, etc.,

L. J. KELLY.

Calcutta.

Sir,

Milk fever syringes are not yet used by all owners, and cases are still remunerative, if properly conducted—not with a bicycle pump and without medicine—to say nothing of the credit one gets from the anxious client. With the kindly help of veterinary correspondents to agricultural papers, preventive veterinary medicine may be carried too far—from the practitioner's point of view; the palmy days promised in the future by "those who know" notwithstanding.—Yours faithfully,

G. F. B.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1313.

SEPTEMBER 6, 1913.

VOL. XXVI.

THE QUESTION OF PRIVATE SLAUGHTER-HOUSES.

This week we print an abstract of a paper and our report of the discussion upon this subject, which formed part of the proceedings of the Veterinary Section at the recent Sanitary Congress at Exeter. The paper was a good summary of the objections to private slaughter-houses and the desirability of public abattoirs; and its main conclusions were unanimously endorsed by the audience—as might have been expected. Everyone conversant with the subject recognises the superiority of public abattoirs to private slaughter-houses for purposes of inspection. But there are very serious obstacles in the way of a general adoption of the abattoir system in England; and, though these were recognised at the Exeter meeting, the discussion revealed no means of surmounting them.

Despite those obstacles, the public abattoir has made such headway of late years in our large cities that its adoption by smaller towns seems only a question of time. We think, too, that wherever a public abattoir is established it will tend to supersede the private slaughter-houses gradually, though not perhaps very rapidly. Though legislation may succeed in abolishing private slaughter-houses in urban districts, it is quite likely that they would disappear in time without it. But the essential difficulties lie in the country—in those “immense rural areas containing numerous slaughter-houses, in which unsound meat is rarely or never found or reported.” The theoretically ideal way of dealing with these, of course, would be to establish a little abattoir in every village which now supports a butcher; but the present generation will hardly see that ideal realised. It should, however, be possible to have all rural slaughter-houses registered and inspected, and to do so, not by local regulations, but by Act of Parliament, embracing the whole country.

At present, in most rural districts in England, there is practically or absolutely no meat inspection at all. Legislation to establish it as a national system appears to be the first step necessary.

Such legislation will not be easy. Some opposition may be expected; and, further, there will be a difficulty in drafting regulations which, in the rural districts, will be at once effective and workable. In this connection possibly such bodies as the new Veterinary Inspectors Association might note some hints which fell from Prof. Penberthy, the Chairman at the Exeter meeting. A conference which could advance “suggestions which would render an Act of Parliament practicable,” especially with regard to the country districts, might do incalculable good: for at present the general desire for legislation on the question is accompanied by much dubiety as to the possible form.

THE PREVENTION OF MILK FEVER.

I have been deeply interested in the discussion on this subject initiated by Mr. Blackwell, and contributed to by other practitioners, and it is owing to your request for notes on clinical experience and the hope expressed by these gentlemen that the matter might be further discussed, that I am encouraged to send you the following rough notes on the subject.

During over thirty years experience in provincial practice I have seen my share of milk fever, although, I must confess, I am not like your correspondent, Mr. Kelly, I have never known it of daily occurrence.

It is not within my province to discuss the disease or its treatment, but to adhere strictly to the text. Of course I have seen cases of milk fever at all times of the year, but during the hot dry summer of 1893 I only saw three cases during June, July, and August, and two of these were in pampered Channel Island cows. During the same period the year following, when the weather was wet and the supply of grass plentiful, I saw eighteen cases in the same district. These facts impressed me considerably.

My experience teaches me that neither the removal of the calf from the cow as soon as it is born, nor the leaving it with the cow, either causes or prevents the disease. Neither does refraining from milking the cow immediately after calving have that effect.

I have found that if the following rules be strictly carried out the cow will not go down with milk fever.

I advise that a suspicious cow (every practitioner will know what I mean) be taken up and stabled a fortnight before she is due to calve. She should be sparingly fed and regularly exercised for an hour daily.

A week before her time is up, she should be given a mild aperient drench. At the time of calving, her stomach should be fairly empty.

After calving she should have another aperient drench and be allowed some gruel and treacle to drink. Enough milk may be at once taken to supply the calf, but the udder *must not be stripped* until after the third or fourth day. She may then be gradually brought to full rations and properly milked out.

It is only in very rare cases where the udder is abnormally distended that I advise any milk being taken before calving.

I am aware that no positive proof of the prevention of the disease is possible, but when one has

seen heavy fleshed, deep milking cows, which have been down with the third calf, calve safely through with the fourth and fifth, one is inclined to the conclusion that there is *something in it*. Some of these ideas may appear old-fashioned, but perhaps, for once, they are none the worse.

The drawbacks to this treatment are:—Firstly, the difficulty in getting your instructions carried out. Secondly, the fact that the cow *does not fully come to her milk for a few days after calving*.

Has the latter anything to do with her not going down?

JAMES SMITH, M.R.C.V.S.,

Wetherby, Yorks.

PHYLACOGENS AND STRANGLES.

In June of this year I had an outbreak of strangles, one horse after another going down at intervals until the middle of July, and having lost two horses—one from purpura and the other from the bursting of a post-pharyngeal abscess into the trachea—I thought we were clear.

However, on August the 2nd another horse was affected with submaxillary and post-pharyngeal abscesses; the former of which I lanced, and the latter I burst by pressure, and on going through the stud (30 shires) with the thermometer I found four more with temperatures ranging up to 104 F.

As harvest was imminent this was a serious matter for my client. I advised injecting with phylacogens (P. D. & Co.), and my advice was acted upon, viz., to inject all the horses as well as the symptomatic ones.

On August 6th I injected the whole of the horses on the farm, and in addition six four-year-olds up from grass, these latter before coming in contact with the others.

As a *curative* I gave the five affected horses 30cc. subcutaneously in the neck, and as a *preventive* 15 cc. to the in-contacts and the six horses up from grass.

The result was highly satisfactory. The horse (aged) with the abscesses commenced feeding the next day, and made an uninterrupted recovery. Convalescence was very rapid, and he was at work in ten days.

The horses with the temperatures, dropped to normal, and were at work in three days, and of the rest, I have had no more cases, and they have just gone through a most strenuous harvest.

I am using phylacogens on a case of poll-evil. It is doing remarkably well, but will give the result later on.

“M.”

L'Echo de Paris publishes the following telegram from Brest:—“The Germans are making a veritable clean sweep of Breton horses. They attend all the big sales. It is known this year that they have purchased or caused to be purchased about 180,000.

ABSTRACTS FROM FOREIGN JOURNALS.

THE PATHOGENESIS OF FOOT-AND-MOUTH DISEASE.

Joseph Böhm, of Nürnberg, an official veterinary surgeon, publishes (*Deutsche Tier. Woch.*) an article upon this subject. He calls attention to the pathogenic importance of the young layers of horn lying above those tissues of the foot which are primarily affected with lesions of foot-and-mouth disease. These young layers imbibe infective matter from the primary lesions; and, when they afterwards become exposed to the air in consequence of wear or separation of the horn, they may lead to fresh infections.

Zschokke examined the claws of cattle which had undergone foot-and-mouth disease some time previously. Within the ball of the foot and the horn of the hoof he found cleft-like spaces, which he regarded as residues of a previous accumulation of exudate in the cutis. By means of small portions of the horn of animals which had been affected with foot-and-mouth disease ever eight months before, he succeeded in infecting other cattle with typical foot-and-mouth disease after five days.

The chemical composition of the horn-tissue together with the natural heat of the body, forms especially favourable conditions for the maintenance of the virus. Recognition of this explains the frequent appearance of new outbreaks of infection.

Careful attention to the claws is therefore of the utmost importance. At shows and markets, only animals the condition of whose claws is unexceptionable should be admitted. Similarly, regard should be paid to the possibilities of infection from the claws of slaughtered animals.—*Münchener Tier. Woch.*

TUBERCULOUS GROWTHS UPON THE SEMILUNAR VALVES OF THE PULMONARY ARTERY IN A COW.

Giovanelli reports (*Schweizer Archiv.*) the case of a heifer eighteen months old with the following history. Her mother was killed after being successfully fattened for the butcher, but was found post-mortem to be severely affected with tuberculosis. The calf thrived well up to the age of eight months, when, without any apparent cause, she developed a dry laborious cough. This disappeared in time and the heifer's general condition became perfect. She was fat when taken from the pasture and housed; but, two months later, she began to go wrong. The appetite became capricious, and the animal grew thin, while the owner noticed the appearance of a slight dyspnoea whenever she walked.

Giovanelli then examined her, and found her thin when compared with her neighbours. Her eyes were bright. She ate hay given to her slowly, but continuously. Her general health did not appear to be altered. Giovanelli then had her walked rather quickly upon the road; during which she suddenly stopped, and could only be got back to the byre with difficulty. The respirations were now accelerated, and were abdominal in type.

Auscultation of the lungs revealed nothing abnormal. The whole of the cardiac region was sensitive to pressure. The sounds of the heart were obscured by abdominal borborygmi, and were therefore difficult to perceive.

These alarming symptoms disappeared very quickly, and the heifer again began to feed. Giovaneli, however, seeing that she was the produce of a tuberculous mother, regarded her also as tuberculous, and advised slaughter. About three weeks later she was sent to the abattoir, about a quarter-of-an-hour's journey from the byre. On the way she fell down upon the road, and died suddenly.

Post-mortem, the abdominal organs were found to be healthy. Upon opening the thorax, the pulmonary artery was seen to be voluminous externally. Internally, it was found to be lined with irregular fibrinous deposits. The edges of the valves bore yellowish-grey proliferations with irregular surfaces, and of the size of a pea or of a lentil. Their sectioned surface showed an elastic consistence, and at some points they appeared horny. Upon their surfaces, dirty-white deposits of fibrin were seen, while the face of the valves which responded to the heart was smooth and shining.

Some subcutaneous lymphatic glands were hypertrophied, and contained a yellow mass, caseous, and partially calcified, in which tubercle bacilli were found.—(*Annales de Méd. Vét.*)

RUPTURE OF A THORACIC ŒSOPHAGEAL DIVERTICULUM IN THE HORSE.

F. Volkmann, of Munich, records the following case of an eight-year-old Belgian gelding. The day before the illness the animal had been in harness, had come into the stable again fresh and healthy, and had completely cleared up his evening ration. In the morning he refused all food, taking only a little water. From the stupid appearance of the animal, the owner suspected an affection of the brain.

Volkmann examined him the same day, and found that his general appearance already showed all the symptoms of a very severe illness. He stood in the stall with sunken head and half-closed eyes, and when forced to move, did so sluggishly and with difficulty. The rectal temperature was 103.5 F. The pulse was from 84 to 88 per minute, uniform and regular, and not particularly strong. The respirations were from 36 to 38 per minute, were of the costo-abdominal type, and were not markedly laboured. The visible mucous membranes showed a reddish-yellow colouring. Some slimy discharge was flowing from the right nostril, but the expired air showed no abnormal smell. Auscultation yielded friction sounds on both sides of the chest over the whole auscultatory surface. Volkmann diagnosed the case as bilateral pleurisy.

The next day the general condition of the horse was worse. When forced to move his gait was staggering, especially in the hindquarters. The temperature had risen to 105 F. The pulse rate was 108 per minute, the pulse itself was small and

irregular, and the action of the heart was tumultuous. The respirations were 50 per minute, had increased in violence, and were accompanied by great heaving of the flanks. Auscultation yielded no respiratory sounds in the lower third of the chest on either side. Elsewhere friction sounds, with sharpened vesicular breathing, were audible. A slimy nasal discharge flowed from both nostrils, and the expired air had a faint sweetish odour. The nasal and oral mucous membranes showed a reddish-blue colour, and the conjunctiva a dirty reddish-yellow. Another new symptom on this second day was increased defecation, the faeces being thin and fluid. Volkmann now extended his diagnosis to bilateral pleurisy and septicæmia.

About six hours after this second examination, and about thirty-one hours after the first symptoms of illness had been seen, the horse died of cardiac failure.

The post-mortem examination, carried out next day, resulted as follows: When the thorax was opened, about six litres (roughly 10½ pints) of dirty yellow fluid mixed with alimentary matter escaped from it. The internal walls of the thorax on both sides showed a diffuse dusky reddening, and were completely covered with small green particles of food. The visceral pleura were grey, as if coated with hoar-frost. The right lung showed obstruction—œdema, but the left lung was without alteration.

The passage of the œsophagus through the diaphragm was surrounded by a cicatrous ring. In front of this the thoracic portion of the œsophagus showed a spindle-shaped expansion for about a foot of its length. Its walls were dilated, and their muscular tissue was markedly lighter in colour than was normal, and showed a slight degree of hypertrophy. The mucous membrane of this dilated portion of the œsophagus was rough and thickened.

This œsophageal diverticulum was burst along the whole of its length. The fluid part of the contents of the stomach had then been able to gradually flow out into the thorax, and thus the severe illness had been caused.

Volkmann suggests that the rupture of the diverticulum may probably have been caused by an attack of coughing when it was distended with food.—(*Münchener Tier. Woch.*)

URETHRAL CALCULI IN A MARE.

Eggink records (*Tydschr. v. Veeartsenijkunde*) the case of an eight-year-old mare, which was under his treatment for incontinence of urine. The year before she had given birth to a hydrocephalic foal, the extraction of which had necessitated an ovariectomy. The mare had recovered rapidly from this, but at the end of a certain time she had commenced to urinate frequently, and finally developed incontinence.

When Eggink examined the mare he found that whenever she moved, a certain quantity of turbid urine flowed from the inferior commissure of the vulva. The skin beneath was considerably irritated, and the hairs had fallen from it. The mare had

become rather thin, and the appetite had diminished; on the other hand, thirst was greatly increased. The case had been abandoned as incurable by another veterinary surgeon, who had diagnosed a paralysis of the bladder.

Upon vaginal exploration Eggink found a hard tumefaction, the size of a goose's egg, upon the floor of the vagina. Introducing his finger into the bladder, he recognised the presence of a firm mass composed of numerous fragments corresponding perfectly with one another, and occupying the whole of the visical cavity. By means of his right index finger (the left hand meanwhile manipulating the bladder externally) Eggink withdrew a series of calculous fragments ranging from the size of a nut to that of a large walnut. The various fragments bore facets articulating perfectly with adjacent fragments. The bladder also contained a certain quantity of fine gravel.

The bladder, the walls of which were considerably hypertrophied, was irrigated with a tepid solution of boric acid till all the gravel was expelled. The mare was also given ten grammes (equal 5iiss.) of salicylic acid twice daily. Every three days the bladder was irrigated with weak antiseptics, especially a one-half per cent. solution of nitrate of silver. Later, a one-half per cent. solution of sulphate of zinc was used, and then permanganate of potash at the same strength. Later still, the mare was given ten grammes of salol twice daily.

The animal's condition rapidly improved. The appetite returned, and the urine, which was still turbid at first, soon became clear. After six weeks the mare was cured.

Eggink thinks it probable that the embryotomy practised the year before had produced a traumatic vaginitis, from which an infection of the bladder had taken place. Vesical catarrh, and the formation of calculi, had been the consequences of this infection.—*Annales de Méd. Vét.*

W. R. C.

HUMAN TUBERCLE BACILLI IN THE MILK OF A VACCINATED COW.

The persistence with which human tubercle bacilli had inhabited the milk of a cow, raised a strong presumption that the milk of others would have contained living tubercle bacilli, and showed the importance of testing the milk of all cows which had been vaccinated as calves.

The opportunity of testing the milk of two such heifers occurred, and in the milk of one, human tubercle bacilli was demonstrated.

The heifer was vaccinated when she was four days old, presumably with a minimal dose, intravenously. She calved when she was two years and four months old, and some of the first milk from each of the four quarters was obtained for examination. From guinea-pigs inoculated with it which became tuberculous, a culture of human type was isolated. Forty days later a similar result was obtained, the animal was then destroyed.

Post-mortem nothing of a tuberculous nature was found in the udder or supramammary glands, the

mucous membrane of the milk sinuses and ducts was normal, as was also the milk in them to all appearance.

The heifer had reacted to the tuberculin test on three occasions, namely, 7, 12, and 28 months after the protective inoculation.—*The Journal of Pathology and Bacteriology.*

FIBRINÆMIA.

When thrombin or thrombokinase is injected intravenously into rabbits, separation of fibrin takes place in the circulating blood.

The immediate cause of the separation of fibrin is in all cases the action of thrombin.

According to the rapidity with which thrombin is formed:

(a) Clotting occurs in the heart and great blood-vessels, especially on the right side of the heart, following the course of the fluid injected: or (b) masses of fibrin appear in the smaller bloodvessels and capillaries. The former accompanied by the latter, takes place if separation of fibrin is very rapid; the latter alone if separation of fibrin occurs relatively slowly.

The symptoms produced are in part, if not wholly due to mechanical interference with the circulation.

No evidence is forthcoming of an additional toxic effect produced by the fluid injected.—*The Journal of Pathology and Bacteriology.*

[The above appears to the transcriber to have a material bearing on the lesions and symptoms of the class of diseases in the horse which simulate beri-beri, and those in which the scleratomata appear to take a part].

ROYAL SANITARY INSTITUTE CONGRESS. CONFERENCE OF VETERINARY INSPECTORS.

TRANSMISSION OF DISEASES BY ANIMALS TO MAN.
By A. H. ARCHER, M.R.C.V.S. (Member)

INTRODUCTION.

Although it is now fairly generally recognised, by both the human and veterinary branches of the medical profession, that many diseases are transmitted by and from animals to human beings, this fact neither receives the practical consideration it deserves, nor is it impressed on the lay community in such a way that its members appreciate the full significance of its teaching, with the consequence that frequently persons are exposed to grave risks and influences, through ignorance or carelessness, of a more or less serious character, which have not infrequently a fatal termination.

In the case of domestic pets, dogs, cats, monkeys, birds, etc., wilful disregard of consequences, and gross indifference to the effects produced on their fellow creatures, must, I fear, be added to the causes operating in the conveyance of diseases from animals to man, or from one human being to another, through the medium of an animal.

In my printed paper it will be found that I have mentioned three ways in which disease is known to be conveyed or transmitted by or from animals to mankind, and give instances or examples of the kinds of diseases so actually communicated, but of course there are many

[These papers appear in full in the *Journal of the Royal Sanitary Institute*].

others which could be mentioned as being spread in like manner.

I have also suggested a fourth possible way in which animals may play the part of carriers or medium in the conveyance of diseases and so contribute to their development in human beings, viz., by what I have termed natural accidental cultivation; and have briefly hinted at the process by which I conceive it possible that this may be achieved. Of course I am well aware that my ideas may not be shared by others who will give what may appear strong and almost conclusive reasons for such objection; but I ask that hasty judgment be not formed without full and unbiassed consideration has been given to these matters.

I have purposely refrained from quoting instances of the transference of disease by members of the animal kingdom inhabiting foreign countries, as I wish to emphasise the importance of the subject under discussion as applying to our own immediate surroundings.

I would also especially direct attention to the transference of disease by domestic pets, and by diseased carcases of the larger domesticated animals, which latter I dealt with, to some extent, in the paper entitled "Notification of Death of Animals," presented at the York Congress last year; and if only some modicum of good results from the puny efforts attempted by the production of this paper, I shall feel that I have not wrought in vain.

Dr. GARRATT, M.O.H., (Cheltenham) said a good many diseases were transferred from animals to men. There was anthrax and glanders. With regard to milk, which they had been discussing so much, a good many diseases were conveyed in milk. There was scarlet fever. In his own experience he had had several instances of scarlet fever being conveyed in milk—not from the cow to the human being perhaps—there was little or no evidence of scarlet fever being so conveyed, but certainly diphtheria had been known to be conveyed from the teats of cows to milk, and thus to human persons. The Medical Officer for Reading some years ago wrote an interesting paper, in which he gave some photographic illustrations of the teats of a cow with ulcers upon them, in which the typhoid bacillus was found. There was the possibility of other diseases being conveyed from animals to man. Recently he saw some tame rabbits in a terrible state of eczema. One was aware that the germ that caused eczema was related to typhoid. These rabbits were suspected of causing disease in that case. As a matter of fact, he had some material examined by the bacteriologist, but he was not able to say it was the typhoid microbe.

Dr. WEBB stated that he could support Mr. Archer's assertion that diseases of animals were communicated to man. He should like to say that in May last a case of diphtheria was reported to him in a row of seven houses. On investigation the case was found to be a child seven years of age. He examined her throat, which showed bacilli. Enquiry elicited that she had been in the habit of taking the cat to bed every night. He suggested that the cat should be destroyed, and it was destroyed. He took some swabs from the cat's throat, and examined them with the aid of a microscope. They showed a mixed infection. Investigation also showed several other cats in the neighbourhood to be affected. They were all destroyed.

Mr. DIXON said any one who had had experience of this matter was in duty bound to contribute to this discussion. Anthrax caused throughout the country, as it did in Leeds, a considerable amount of interest. They frequently had reports from factory inspectors for the Home Office on outbreaks of anthrax occurring in leather works. The authorities immediately made enquiry at the leather works where they received hides

from slaughterhouses, and in most cases foreign hides. They found that anthrax cases occurred among the people who worked the foreign hides. They frequently had reported to them that anthrax had occurred within the last day or two at a farm in the country, from which milk was sent into Leeds. It seemed to him a fatal defect of the Anthrax Order that it should not be compulsory on the local authority concerned to notify the M.O.H. of the place where the dairy's milk was consumed. They had reason to suppose that there might be a cow in a farm suffering from anthrax, and some of the anthrax bacilli got into the milk. Such was their rule in Leeds that when they got to know that a farm had had anthrax they watched the cows to see that they were healthy before the milk was despatched to the town. Anthrax was a dangerous and deadly disease, and more care should be taken with regard to its existence in dairy cattle, and it was most essential to inform the district in which the milk was consumed.

As to scarlet fever, they all remembered the Hendon outbreak, which gave rise to so much concern. Scarlet fever was an instance where the veterinary inspector and the medical officer of health could work in such splendid uniformity and companionship. The medical officer and the veterinary officer each attended to his duties and then met afterwards to confer. In several cases they had failed to find anything to connect cows with scarlet fever, but they had always been able to put their finger on the source of infection—the milker.

The diphtheria point was interesting and important. He remembered reading an account some years ago by a veterinary surgeon on this question of diphtheria and milk. To him it seemed proved that the cow got the bacillus. The cow had not suffered from diphtheria, but had served as a medium on which the diphtheria had grown in the form of an eruption on the udder.

Dr. HAY (Bridport) rose to a point of order, and said he did not quite see the relevancy of Mr. Dixon's remarks. If Mr. Dixon was prepared to give them some instances of disease being transmitted in some uncommon way there might be some object in it. Every one knew that diseases were transmitted from animals to man. If they discussed that question they would be there from then till doomsday.

The PRESIDENT replied that on the point of order he must rule that Mr. Dixon was thoroughly in order. (Hear, hear.) He was giving them now such first-hand information as they were desirous to collect to lay before the medical profession and the public generally. This was the sort of material they wanted. The bacterial methods might be a little more precise, but they did want to hear about ordinary operations in one of the most reliable centres in the country.

Mr. DIXON, proceeding, said an epidemic of sore throat caused great alarm. He was instructed to go to the farm and render what aid he could. He met the resident medical officer, and together they investigated the case. The milk supply was suspected, but he could not find anything in that. They found, however, that the cows were acting as carriers of septic infection from a contaminated drinking pond. When the milk was sterilised the epidemic immediately ceased, and there had been no more sore throat.

Glanders was a danger also, and they were able to deal with many cases of glanders in large towns.

Dr. HILL (Durham) said in Central Africa there were instances of sleeping sickness being transmitted from animals to man. In other tropical regions he had heard of transmission from cows to horses.

Dr. BARLOW (Wallasey) said tuberculosis was easily communicable to guinea-pigs.

The PRESIDENT: Give us any specific instances which are likely to increase our knowledge of the subject.

Dr. BARLOW: I have heard nothing yet to increase my knowledge.

The PRESIDENT: I am extremely grateful for the information I have obtained.

Mr. W. ASCOTT said it was within his own knowledge that milk could contain anthrax bacilli. In one particular case where he was called to a cow which died while he was present, he took samples of the milk, which was full of anthrax bacilli. The milk taken overnight was full of anthrax bacilli.

Mr. A. H. ARCHER (Southsea) in reply, said his own experience in which animals had communicated disease to men, either by directly or by acting as carriers by their excreta or other material got on their coats. Even with a canary the bird was taught and allowed to pick out of the owner's mouth, and when the bird was affected with disease it could be conveyed in that way. He had had quite a number of parrots transmitting disease, such as diphtheria and throat diseases, and even scarlatina, with their bill or by means of their feathers. Mr. Male had asked a question with regard to the transmission of diphtheria from dogs. He had met with cases in which diphtheria had been transmitted from animals to human beings.

PRIVATE SLAUGHTERHOUSES, PUBLIC ABATTOIRS, AND FRIEBANKS, by HERBERT PECK, M.D., C.M., D.P.H., Barrister-at-Law, Medical Officer of Health for the Chesterfield Rural District (member). [Abstract]. Submitted by Dr. HERBERT JONES.

This important subject would be more frequently discussed but for the powerful representation of the meat trade on many sanitary authorities. The insecure conditions on which many sanitary officials hold their appointments frequently prevent them from taking action they know to be desirable, but which would bring them into conflict with members of their councils and probably end in disaster, or at least in loss of prestige.

The main objections to private slaughterhouses are:—

1. The driving of cattle through the streets to the public danger. This is a serious matter in towns, and should not be permitted. The practice also causes suffering which would not be undergone in transit to an abattoir properly served by a railway siding. I have frequently seen pigs lying in a street in a state approaching collapse from the fatigue of a half-mile journey from a railway station to a slaughterhouse.

2. Many slaughterhouses are situated in crowded localities, so that a nuisance of sound or smell is unavoidable. Many do not conform to the model bye-laws of the Local Government Board, which should be regarded as the minimum requirement. Regulations, where such exist, are not always scrupulously or promptly observed, and a nuisance from offal or flies results. What may exist is shown from the following description of a private slaughterhouse taken from the annual report of Mr. Parker, F.R.C.V.S., Veterinary Inspector for Newcastle-on-Tyne:—

"One afternoon, during July last, on entering a slaughterhouse premises within the city, they were found in a filthy condition, dirty sacks and old boxes full of old bones flyblown and filthy were scattered about; a refuse cart standing in the yard was simply overloaded with filth. Part of these premises were used to prepare cooked meat. On entering the fat-mincing room, a large bath was found containing 1 cwt. 104 lbs. of intestinal and other fat, literally alive with maggots. In a tin near the bath was found 1 cwt. of the same fat, also alive with maggots. In another tin was found 1 cwt. 24 lbs. of fat which had just been put through a machine driven mincer, the maggots in this case being ground up with the fat. Large maggots were crawling about the

floor. According to the manager, it was intended to mince the whole fat and then boil it down for dripping, to be sold for human consumption."

Many rural districts are without bye-laws, and it is unusual to find a slaughter-house in them which is satisfactory in all respects.

3. The difficulty of inspection. This is the main objection. The sanitary officials of a town with many private slaughterhouses cannot possibly inspect them all in one day, and as butchers usually kill all on one day, they can inspect only a portion of the meat produced. Some butchers slaughter at night, which puts the presence of an inspector out of the question, except in rare cases. Animals about which there is any doubt are slaughtered at unusual hours.

If these objections apply to a town where the slaughterhouses are comparatively near together, they do so to a much greater extent in country districts. Efficient inspection in these is impracticable. There are immense rural areas containing numerous slaughterhouses, in which unsound meat is rarely or never found or reported. This is not the worst feature of rural slaughterhouses. Dishonest butchers, trading in a town where careful supervision exists, do not kill in the town, but in some neighbouring district where sanitary administration is less efficient. A case recently came to my knowledge in which a man killed good cattle in his slaughterhouse, while he killed others, brought at "screw" prices, at one in another district, registered in the name of another person.

It must not be assumed that all butchers are dishonest and anxious to put off bad meat at the price of good, but I do not hesitate to say that nothing but a fraction of the bad meat produced is ever seized or surrendered. Obviously diseased parts are removed from an unsound carcase in the great majority of cases, and the remainder sold for human consumption. This is proved sufficiently well in the absence of the figures for private slaughterhouses by the difference between the practical nil of the rural districts and the percentage found diseased in public abattoirs.

The German Imperial Law of 1900 regulates the sale of meat, and contains many beneficent precautions. It is too long for even partial quotation, but should be studied by all sanitarians. Under it, all animals are subjected to ante-mortem, as well as post-mortem, examinations, although the former may be foregone in cases of emergency, which are defined, and also the latter when the animal is killed for the use of the owner's household. The fees are moderate. In North Germany they are 2 marks for an ox or horse, 1 mark for a pig, and 75 pfennigs for a calf, sheep, or goat.

Systematic inspection should be adopted in this country. To ask for it is to ask for nothing new. It was practised in Ancient Babylonia, Greece, and Rome; by the followers of Moses and Mahomet; it obtains today in Germany, Belgium, France, Holland, Spain, Italy, Austria-Hungary, Roumania, and Switzerland. Great Britain, especially its southern portion, should "wake up!" Why should England lag behind Ancient Babylonia?

The improvement that follows regular inspection was well shown in the case of a town for which I was medical officer of health. There were for many years a number of butchers who brought inferior meat to the weekly open-air market, and sold it at low prices. Much of it, in the absence of microscopical evidence, could not be seized as diseased, but whenever it could be positively recognised as such, it was seized and the vendor prosecuted. The magisterial bench supported the sanitary authority, and inflicted such salutary punishment that the number of butchers keeping stalls in the market decreased from 50 to 37, and it became possible for a person to buy in that market and be reasonably sure of getting something fit to eat. Sixteen

to twenty butchers had stalls in a weekly open-air market in my present district at the time I took up my duties. The reputation of the meat exposed for sale may be inferred from the remark of a butcher when I seized some of his meat, on what was by a coincidence the first occasion on which either of us had visited the market: "Why, I was told I could sell anything here!" Regular inspection by myself at first, and by a resident inspector later, reduced the number of butchers attending the market to two, to the advantage of the local tradesmen. The traffic still goes on, and the same men as formerly are engaged in it, but in other markets. An inspector, who was instrumental with myself in getting three months hard labour on two occasions for a "slink" butcher, meeting him recently, said: "Where have you been this long time?" and received the answer: "Selling in a place where we never see an inspector, and where an honest man can drive an honest trade!"

All that is condemned is a loss to the butcher, but probably a greater loss to the farmer, for the butcher protects himself by giving low prices for inferior stock. The ultimate loss falls on the community. If the amount destroyed was greatly increased, the price of meat would rise, but something can be done by the institution of the Freibank, where the meat of inferior quality by reason of age or disease, is sold after being rendered wholesome by cooking, pickling, or in other ways. There was one in Augsburg in 1276, another in Hamburg in 1375; they are now common in Germany, and have been established in Belgium, France, and Italy. They render saleable large quantities of meat which would otherwise not be used as food, or would be so used without being rendered harmless.

The averages for the Kingdom of Saxony for the years 1894, 1896, and 1899 were: Animals killed, 887,770; admitted to market without restriction, 99.24 per cent.; destroyed, 0.13; delivered to the Freibank, 0.71. These figures show that more than 84 per cent. of the diseased meat was rendered fit for consumption.

There were utilised on the Freibank in Leipsic in 1891 the meat of 604 cattle, 89 calves, 28 sheep, 983 hogs, and 104 parts of carcasses, which weighed 271,609 kilogrammes, equal to 598,626 lbs., or 267 tons.

Dr. MILLER (Hereford) in seconding the resolution, said there was no doubt whatever of the value of the public slaughterhouse, and he thought the time had come when there should be public slaughterhouses throughout the country, and private slaughterhouses abolished. (Hear, hear.)

Dr. GARRATT (Cheltenham) said he hoped that Mr. Burns would bring in a Bill, either in connection with something else or independently, which would lead to the establishment of public abattoirs in all towns and the abolition of private slaughterhouses. He was sure that that could not be done except by some definite set legislation. (Hear, hear.)

Dr. WEBB said in his opinion, and in the opinion of all men engaged in meat inspection, this was nothing more nor less than a farce. It was impossible to inspect in any area of any size where slaughtering went on at all times. His experience was that there were a certain number of men who bought on what he called the "off chance." If it was tuberculous it went through, and they made money. In his district it was absolutely impossible to inspect meat adequately. In his opinion this was a State question. The whole thing should be taken in hand by the Government. Regulations should be made hard and fast for every district—rural, urban, and county borough. He would make an Order to hall-mark the meat, so that if it was moved from one place to another it would be recognised.

Alderman A. SHELMEKDINE (Liverpool) said his experience was that butchers' slaughterhouses were held by certain people whose licenses, under an old Act of Parliament, held good for the life of the individual. They had found in years gone by that animals in the last stage of tuberculosis had been taken to these private slaughterhouses and slaughtered, say, at four o'clock on a summer's morning, and that meat was dressed so that it could be sold as cheap meat. It was only on the death of the licensee that anything could be done.

Mr. C. CASH thought Dr. Peck had made a strong case for slaughterhouse reform. He came from a town where they had been fighting for a public abattoir for fifty years, and where the authority was as far from getting one now as when they started. Other towns were in the same evil plight. Petitions for it always failed against the organised opposition of the trade, and before they got through the difficulties of the site, the cry of increase of the rates was raised. It seemed to him that the only way in which this matter could be satisfactorily dealt with was by legislation. (Hear, hear.) A Bill passed in Germany in 1868 empowered any municipality to abolish a private slaughterhouse after due notice given.

Mr. LUDD remarked that it fell to his lot to visit slaughterhouses from week to week, and he could assure them that many of them were a disgrace to any town. Some were not more than ten or twenty feet away from private houses. He was sorry that the Councils did not move as fast as they ought to. They had butchers and slaughtermen on the Councils, and those present knew what the meaning of that was. If the inspector was a bit nervous, he was afraid to bring forward any complaint, and if he did bring it forward he was told that he had to see that the place was kept clean. It was impossible. Butchers were there early mornings, sometimes late at night, and sometimes on Sundays. If it was a bad bullock it was taken in on a Sunday. These were the things existing in some of the private slaughterhouses, and the sooner they were done away with the better it would be for all parties concerned. With regard to the rural districts, he questioned whether the cattle were taken to slaughterhouses at all. They had been killed in the linbay or the barn and had been cut up and sent to the larger centres, and nobody to look after it. He supported the resolution with all his heart, as he had supported the idea for more than twenty years.

The PRESIDENT said he should have been glad if the meeting had made suggestions which would render an Act of Parliament practicable. It was much more convenient to go to a butcher and examine the meat in a public abattoir. But they must cast their minds back to the name of the gentleman who spoke last. Even in a place of 10,000 inhabitants an abattoir could be economically arranged. He did not oppose the resolution, which had so much in its favour from the point of view of public health, that if there were not the obstacles noticed in the paper, and by the framer of the resolution, the thing would have been done twenty-five years ago. They must not suggest to one portion of the community (the agricultural portion) that they were all dishonest, but there were great difficulties associated with it, and if they could send to Mr. John Burns to say how the Local Government Board could deal with the country districts they would get an Act passed as soon as possible. Some of the difficulties were extremely real, desirable as he thought the purpose of legislation on the subject would be.

Mr. W. LOVE (Lanarkshire) said they had erected abattoirs in Lanarkshire all over the county, and their experience had been that since they had made these

erections and had proper inspection by competent men, many diseased animals had been found to come in from the other counties, but as they were condemned the owners had no return for their diseased cattle.

The PRESIDENT said they did not want any more piece-meal legislation. They wanted the whole thing uniform. (Hear, hear.) They would have to spend a large sum in compensation to the owners of private slaughterhouses.

Mr. MALE: I should like to see it more explicitly stated who is to carry out the inspection.

The PRESIDENT: I don't think that that is before you.

Mr. J. CRATHORN (Paignton) said if the Councils were willing to pay compensation, and to meet the cost of public slaughterhouses, he did not see any difficulty whatever in obtaining a private Bill. He represented a small district of about 12,000. Two years ago they were promoting a Bill for other purposes, and they had one or two clauses put in dealing with the abolition of private slaughterhouses at the expiration of three years, and giving the Council power to build an abattoir. If they could get that in a small district, he did not see why larger places should not be able to do it.

Dr. GARRATT (Cheltenham) pointed out that occupiers and owners of private slaughterhouses claimed enormous sums by way of compensation. They wanted a direct means of dealing with the question. He supposed the Inspectors of the Local Government Board would have some practical suggestions to make with regard to authorities in small places where slaughterhouses existed; he should say that these slaughterhouses should be licensed, as they proposed to license a milk place, that they might be kept under supervision. Lanarkshire had shown the way. Presumably some such system also existed in France. There was nothing to prevent slaughterhouses on absolutely sanitary lines being erected by public authorities.

The PRESIDENT pointed out that local authorities had the powers, but they were not compulsory.

Dr. GARRATT: We have no powers to compel butchers to use the abattoirs.

Dr. H. JONES, replying to the discussion, remarked that as a fact there was no law in regard to the regulation of slaughterhouses in rural districts. A man might erect a slaughterhouse without being registered or licensed at all and unless the rural districts had applied for and obtained urban powers there was no control over him. The next point is that it is idle for Liverpool or for any other district, to spend thousands of pounds in erecting public abattoirs if in the area outside their district butchers might sell with impunity without any form of license or registration at all. (Hear, hear.) In Cardiff, where there was not a single private slaughterhouse, they found that the usefulness of the abattoir was enormously lessened, because people simply went out into the rural districts and did what they pleased. Years and years ago, when the Public Health Act was first brought in, it seemed to be thought that the sanitary districts could keep to themselves within a sort of ring fence, and that they had nothing to do with anyone outside. If it was the case at that time, it certainly was not the case now. If there was one question which should be treated nationally it was this question of slaughterhouses. (Hear, hear.) The first thing the President of the Local Government Board would have to do was to see that in rural districts slaughterhouses were regulated. The laws with regard to slaughterhouses should be the same all over the country, they must treat it absolutely as a national question. (Hear, hear.) He thought the point that they ought to carry home with them was that in Lanarkshire they had erected public slaughterhouses in rural districts. Scot-

and was ahead of them in England in this, as in many other matters. The only way in which they could get out of many of the difficulties was to give their officials security of tenure. (Hear, hear.)

The resolution was carried unanimously.

This concluded the business of the Conference.

SECTION A. SANITARY SCIENCE AND PREVENTIVE MEDICINE.

THE PREVENTION OF HUMAN TUBERCULOSIS OF BOVINE ORIGIN (PARTICULARLY FROM THE POINT OF VIEW OF THE TUBERCULOSIS ORDER, 1913), by WILLIAM G. SAVAGE, M.D., County Medical Officer of Health, Somerset.

This problem involves three considerations:—(1) The extent to which human tuberculosis is of bovine origin; (2) The prevention of human infection from bovine sources; (3) The diminution of bovine tuberculosis.

As regards the relationship of bovine to human tuberculosis, and the intercommunicability of the two types, I do not propose to make any extended remarks. Every person who has read the careful experiments and deductions of the last English Royal Tuberculosis Commission, backed up and confirmed as they are by numerous experiments carried out in other parts of the world, can have no doubt of the relationship, although there is still room for discussion as to the amount of human tuberculosis of bovine origin.

We may accept the words of the Royal Commission.

"There can be no doubt but that in a certain number of cases the tuberculosis occurring in the human subject, especially in children, is the direct result of the introduction into the human body of the bacillus of bovine tuberculosis; and there can also be no doubt that, in the majority at least of these cases, the bacillus is introduced through cows' milk. Cows' milk containing bovine tubercle bacilli is clearly a cause of tuberculosis, and of fatal tuberculosis, in man."

We are not yet in a position to definitely state the proportion of human tuberculosis of bovine origin, although data are steadily accumulating. In my opinion the most reliable estimate is that based upon the determination in human cases of the types of tubercle bacilli present.

Apart from exceptional circumstances, bovine infection to man is spread entirely from tuberculous meat and milk, including milk products. Of these, milk, and to a less extent butter, is by far the most important, and must be regarded as the main vehicle of infection.

Considering milk alone, the second consideration resolves itself into, How far can human infection be prevented from tuberculous milk?

Roughly speaking, not less than 10 per cent. of ordinary milk samples contain tubercle bacilli in an active virulent condition (to the guinea-pig). In milks sent to Sheffield, for example, examined in 1911, the percentage was 9.8; in London for the same year 10.8 per cent.

These bacilli are derived from cows suffering from tuberculosis; but, as is well known, not all tuberculous cows excrete tubercle bacilli, but only those which are "open" cases of tuberculosis. For practical purposes such cows comprise three groups: (a) advanced cases of tuberculosis; (b) cows suffering from tuberculosis of the udder; (c) cows suffering from "open" tuberculosis apart from (a) and (b).

Undoubtedly group (b) is the most important source of tubercle bacilli to milk, while group (c) furnishes the smallest number of tubercle bacilli.

The administrative procedure for dealing with these animals is contained in the Tuberculosis Order, 1913,

of the Board of Agriculture, which came into force May 1st last. It is important to consider the extent to which this very important Order is likely to eliminate altogether or to diminish the presence of tubercle bacilli in milk.

In the words of the covering circular of the Board, the Order "aims at securing the destruction of every cow found to be suffering from tuberculosis of the udder, or to be giving tuberculous milk, as well as of all bovine animals which are suffering from tuberculosis with emaciation."

To detect these animals, two lines of procedure were available. On the one hand local authorities might have been required to arrange for systematic inspection of the cows and bovine animals in the area under their jurisdiction, with the view of finding the above classes of tuberculous animals; or, on the other hand, all owners of such animals might be required to notify them to the local authority. The second procedure has been adopted, and it is now the duty of those owning such animals to give information of the fact to an officer of the local authority without avoidable delay.

In the practical working of this Order certain criticisms and questions suggest themselves, of which the most important is the extent to which it is likely to result in an elimination of tubercle bacilli from milk. It is clear that only a diminution of the percentage of tuberculous milk, and not a total elimination, is to be looked for.

In the first place, both as regards cows suffering from tuberculosis with emaciation ("wasters") and cows suffering from udder tuberculosis, particularly the latter, it will, I believe, inevitably result that, in at least many cases, there will be a long delay, possibly of many months' duration, between the time these cows become active distributors of tubercle bacilli into milk and their detection by the veterinary inspector of the local authority. During this period not only will tubercle bacilli be added to the milk, but these highly dangerous animals will have abundant opportunities of infecting cows in the herd.

Again, not only will detection be frequently late in the course of the disease, but in the case of tuberculosis of the udder a number of cases will be overlooked and missed. The published opinions of expert veterinary authorities clearly show that even with competent and skilful veterinary surgeons the diagnosis of early tuberculosis of the udder may be a very difficult matter. This point is so important that a few authorities may be quoted in support of it. For example, Dewar says—

"In the udder the progress of the disease is often slow, and there is no doubt but that it may exist for weeks in such a condition as to render the milk dangerous before the most expert clinician could detect its presence."

Nocard remarked that the diagnosis of tubercular mastitis is

"Both urgent and difficult; the clinical symptoms are vague, and generally point to a range of probabilities which are more or less certain. Even if the cow has reacted to tuberculin, it does not necessarily follow that the induration of its udder is tuberculous, for tuberculous cows, as well as healthy ones, are liable to contract mastitis of various natures."

Prof. Delépine, who has had great experience in this problem, remarks:

"Tuberculosis of the udder can be detected with great accuracy by a combination of veterinary inspection of the cows and of bacteriological examination of milk obtained from udders showing signs of disease, more especially enlargement and induration. It is, unfortunately, impossible for the most experienced veterinary surgeon to distinguish by inspection and palpation tubercular mastitis from all other forms of mastitis.

It is also practically impossible for the veterinary surgeon, unaided, to discover by ordinary inspection early tuberculous lesions of the udder."

Delépine, indeed, found in his work at Manchester and working with highly experienced veterinary inspectors, that not more than one third of the udders, which on inspection appeared to be possibly affected with tuberculosis, were on bacteriological examination proved to be actually tuberculous. The Sheffield results afford evidence in the same direction.

Finally, the discrepancy between clinical and post-mortem results may be mentioned. As an example, the following data from a report of Dr. Wilson, county medical officer of health, Lanark, may be quoted. He found that out of 42,024 cows examined in four years by experienced veterinary surgeons only '08 per cent. showed udder tuberculosis. In contradistinction to this, at the Bellshill Public Slaughterhouse, where careful records are kept, the number of cows found to have had udder tuberculosis was about 2.6 per cent. He concludes, as regards udder tuberculosis, that "at present we may assume that less than one-thirtieth of the actual number can be detected."

While certainty in the diagnosis of udder tuberculosis cannot be attained by clinical examination alone, many if not most of the difficulties can be removed by the use of combined clinical and bacteriological examinations. The Tuberculosis Order contemplates the use of such combined examinations; and the Board of Agriculture, in their Circular of March 25th, 1913, directs local authorities to

"Issue instructions to their veterinary inspectors that in the case of cows suspected of having tuberculosis of the udder or giving tuberculous milk; samples of their milk should be centrifugalised and examined for tubercle bacilli with the microscope."

It may be mentioned in passing that while simple microscopic examination is usually sufficient to detect tubercle bacilli in milk samples from individual cows, it is not only quite unreliable for mixed milk samples, but in a certain proportion of single cow samples the bacilli will fail to be detected, particularly if the sample is badly collected.

Summing up the matter as regards tubercle bacilli in milk, it is evident that if the Order is properly and vigorously put into force, there will be a considerable and very valuable reduction in the amount of tubercle bacilli in milk, but very far from a complete elimination of tuberculous milk. Tubercle bacilli will still gain access to milk from the following sources: (a) "wasters" and udder tuberculosis cases not yet reported and slaughtered; (b) missed cases of cows suffering from udder tuberculosis; (c) cows with other varieties of "open" tuberculosis neither reported nor detected.

The benefit is very considerable, but the compensation to be paid is very heavy, and, in my opinion, can only be justified if it is largely a non-recurrent expenditure, or at least one which will very largely diminish within a few years. While everyone admits that the expenses in the first few years will be very heavy and out of proportion to the normal expenditure, it is usually advanced that after a few years there will be a great diminution of the compensation to be paid, due to a diminution in bovine tuberculosis generally, and particularly in the varieties of tuberculosis which have to be notified.

It is clear that the prevention of human tuberculosis of bovine origin cannot be separated from the prevention of tuberculosis amongst bovine animals, and that no steps can be permanently satisfactory unless they definitely aim at a diminution of the total bulk of bovine tuberculosis. I am not sanguine that the present Tuberculosis Order, as it is likely to be put into operation in the different areas, is likely to largely diminish the amount of bovine tuberculosis.

It has been shown above that at least the great majority of cases of udder tuberculosis and "wasters" will not be detected and slaughtered until *after* they have been actively excreting tubercle bacilli for long periods and have had abundant opportunities of infecting other cows in the herd. When the other cows have been exposed to extensive and continuous infection, and a considerable proportion has become infected, the local authority steps in and removes the active centre of infection.

It is much worse than trying to prevent the spread of human tuberculosis solely by the removal of advanced human cases, since the latter can be taught to control their expectoration, while cows are especially sensitive to infection. Also the grossly insanitary condition of many cowsheds greatly favours infection.

Apart from the slaughter of the specific groups of tuberculous animals, the preventive work in the Order is not extensive. Under Article 4 of the Order, as the first circular of the Board remarks:

"The veterinary inspector will be able to extend his examination to any bovine animals upon the premises that have been associated with a diseased animal, in order that he may at the same time take steps to deal with any other bovine animal which in his opinion presents clinical symptoms of tuberculosis."

In their March 25th circular they repeat this advice, and say the examination should be extended to other bovine animals on the premises, and particularly to all milch cows.

The Order itself, section 4 (1) states that any veterinary examinations to be made are such "as in the opinion of the local authority is necessary." Any preventive work of this nature clearly, therefore, rests with the local authority, and the more active they are the

greater the compensation they will have to pay for the first two years.

So far as I have been able to ascertain, most local authorities are looking at the problem from the purely financial standpoint, at any rate in the rural districts.

To work the Order on the best preventive lines, it would be necessary to provide a staff of whole-time veterinary inspectors, who would make it their business to thoroughly examine all herds, the milk from which showed the presence of tubercle bacilli, or from which a notification had been received.

It is, as yet, too early to say what will be done in the different counties, but I believe it will be found that in the majority of cases the Order will be worked with a minimum of expense through the local veterinary inspectors now employed in connection with the diagnosis of disease under the Diseases of Animals Acts, and that active preventive work will not be encouraged. This, of course, is a very short-sighted policy, and will largely result in perpetuating the compensation to be paid.

If this forecast is unfortunately realised, I think we must not accept this Order by itself as likely to play any great part in the diminution of bovine tuberculosis in the bulk, and therefore as being most inadequate, and inadequate in itself. I rather look upon this Order as a first instalment, and possibly goes as far as it is now wise to go, but is incomplete in itself, and must be followed by an extended use of true preventive measures.

These preventive measures must include active educational propaganda, not only to explain to farmers the nature and lines of prevention of tuberculosis in cattle, but also to educate the public to an appreciation of milk free from tubercle bacilli, and should be developed on the lines of assisting the farmer to rear a tuberculosis-free herd.—*Journal of the Royal Sanitary Institute.*

Charge of Cruelty Dismissed.

EXPERIMENT ON A DONKEY.

At Runcorn on Monday last, Dr. Warrington Yorke, head of the Research Laboratory of the Liverpool School of Tropical Medicine, and an expert in sleeping sickness, was charged with cruelty to a donkey by neglecting it.

The evidence of the Police and of the Inspector of the Prevention of Cruelty to Animals Society was that the donkey lay for over a week in a field apparently dying, without shelter from the sun and tormented by flies. It was apparently paralysed and could not move, while there were sores on its hind quarters.

Dr. Yorke's defence was that the animal had been given a new drug experimentally, and felt absolutely no pain while in the field, though an untrained observer might think it did. He killed it immediately the result of the experiment was known. It was fed and watered daily.

The Bench said the Society should have made a more careful investigation. The charge was dismissed with two guineas costs against the Society, whose solicitor intimated that there would probably be an appeal. —The Times.

The Practice of Vivisection.

The Home Office have issued a Return showing the number and nature of experiments performed on animals in England, Scotland, and Ireland during the year 1912 under licences granted by the Home Secretary [270].

Including 16 whose licensees expired on February 29, 1912, the total number of licensees was 598, and of these, 151 performed no experiments. During the year new places were registered for the performance of experiments at Aberdeen, Ayr, Cambridge, Glasgow, Greenwich (the pathological laboratory of the Royal Naval College), and Whitechurch, Glamorganshire. In London, the conjoint laboratory of the Royal Colleges of Physicians and Surgeons at Queen's Square, Bloomsbury, was substituted for the conjoint laboratory on the Victoria Embankment, and the London School of Medicine for Women, Hunter Street, was registered.

The total number of experiments was 83,599, being 11,604 less than in the preceding year. The experiments included in Table IV. (A), in which all serious operations are placed, numbered 5,043, a decrease of 47. Of that total, 2,803 came under the provisions of the Act that the animal must be kept under an anæsthetic during the whole of the experiment, and must, if the pain is likely to continue after the effect of the anæsthetic has ceased, or if any serious injury has been inflicted on the animal, be killed before it recovers from the influence of the anæsthetic. In the case of the other 2,240, the initial operations were performed under anæsthetics, from the influence of which the animals were allowed to recover. These operations are required to be performed antiseptically, so that the healing of the wounds shall, as far as possible, take place without pain. If the antiseptic precautions fail, and suppuration occurs, the animal is required to be killed. After the healing of the wounds, animals are not necessarily, or even generally, in pain, since experiments involving the removal of important organs, including portions of the brain, may be performed without giving rise to pain after the recovery from the operation, and after the section of a part of the nervous system, the resulting degenerative changes are painless. In the event of a subsequent operation being necessary, a condition is attached to the licence requiring all operative procedures to be carried out under anæsthetics of sufficient power to prevent the animal feeling pain, and no observations or stimulations of a character to cause pain are allowed to be made without the animals being anæsthetised. The number included in Table IV. (B) were 78,556, a decrease of 11,557. These experiments, which are all performed without anæsthetics, were mostly inoculations. In no case was a certificate dispensing with the use of anæsthetics allowed for an experiment involving a serious operation. The results in a very large number of these experiments were negative, and the report states the animals suffered no inconvenience whatever from the inoculation. In the event of pain ensuing as the result of an inoculation, a condition attached to the licence required that the animal should be killed under anæsthetics as soon as the main result of the experiment had been obtained.

During the year 24,870 experiments were performed by 24 licensees, working at eight institutions, in the course of cancer investigations. The great majority were almost entirely inoculations into mice. Eighty-two licensees reported over 22,000 experiments which were performed for Government Departments, county councils, municipal corporations, or other public health authorities, and 15 licensees performed over 12,000 experiments for the preparation and testing of antitoxic sera and vaccines, and for the testing and standardising of drugs.

Royal Dublin Society's Horse and Sheep Show.

On Tuesday, 26th ult., in fine and pleasant weather, the great annual Show opened at their splendid premises at Ballsbridge, and on the present occasion the numbers of visitors present early on the opening day, which is devoted entirely to judging, went to show that the function remains more attractive than ever.

The number of horses entered this year marks a substantial increase on last year's figures, chiefly in the hunter classes.

Quality was well maintained. Particularly was this the case amongst the young animals, which made a fine display, and were of great promise. Judging by the attendance of purchasers on behalf of Continental powers, many of these are destined for foreign use. In spite of this drain, it is highly satisfactory to note that quality is being well maintained, largely due to some capital sires which are located in the country, and are proving impressive.

Although this annual show is usually termed "The Horse Show," it must be remembered that from a practical farmer's point of view it includes another and most important phase which is apt to be forgotten. The sheep show is one which should not be ignored, and it is only because of the outstanding importance of the equine section that the other one is sometimes overlooked. Last year, owing to the unfortunate outbreak of "dirty mouth" in cattle, no sheep show was held, but this year we have again the winners at the southern shows, Cork and Maryborough and Athy, competing against the prize takers at Belfast, Ballymena, Newtownards, and other important northern fixtures. That indeed, is where the Dublin Show scores: it comes on near the end of the season, after the local functions have carried out a sort of weeding process. Similar selection occurs in the case of the horses, and the splendidly bred chasers of the Southern half of the island meet in competition with the best that the North can produce. Further, the judges at Dublin are not men who have been accustomed to see the same animals at show after show in any one Irish district or province: they are largely strangers to local Irish shows, and, in any case, their standing is such that one can depend on their judgment being absolutely unbiassed. Thus it is that, apart altogether from the value of the prize money, though that is not to be despised either, a prize at the R.D.S. Show, either in the equine or ovine classes is no small honour, and something of which to be proud. Long may it be so, for so long as it is maintained in its present open and honest manner the proud position of the Dublin Horse Show, as one of the finest in the world, may be taken as unassailable.

In regard to quality, almost all the breeds which were to be seen in the sheep section showed an improvement upon previous years, and particularly was this the case with the Border-Leicesters. It was disappointing that no entries were received for Cheviots, and for Suffolks there were no entries in the shearing ram class. The numbers entered for each breed this year is shown below with those for the last two occasions on which a sheep show was held, bearing in mind that last year (1912) the sheep section was absent.

—The Farmers' Gazette.

Personal.

Mr. D. C. MATHESON, F.R.C.V.S., has been appointed by the Governors of the Royal (Dick) Veterinary College, Edinburgh, to be Professor of Pathology and Bacteriology in the College. At present Mr. Matheson is on the veterinary staff of the Board of Agriculture and Fisheries. He taught in the Veterinary School of Liverpool University for five years and acts as one of the examiners there. He is a native of London.

Mr. W. A. DELLA GANA, F.R.C.V.S., Southampton, acted as judge of the horse shoeing competition at the Arundel, Littlehampton, and District Show, at Arundel Park, on Wednesday, 27th ult.

At the Seventeenth Annual Show of the Ross-shire Crofters' Club, held at Evanton, Ponies—M.I. Type Class, were judged by Capt. Macintyre and Mr. Gair, M.R.C.V.S., Conon.

In the Cattle Section chief interest lay in the tuberculin tested cattle, there being a large entry, and very keen competition.

"A feature of the Crofters' Show was the exhibition of tuberculin-tested cows, in connection with which Mr. Gair, the Conon V.S., has done so much pioneer work in Ross-shire in the past two or three years. It is undoubted that Mr. Gair's enthusiasm and labours have given us, in Ross-shire, greatly-improved stocks of cattle, especially cows for the supply of milk not only for dairies, but for the crofter and farmer's own households. What this means in improved health in the community, as well as improved stocks, cannot be overestimated, and we hope that the testing will be carried out still more extensively in the future. It is gratifying to know that, following Ross-shire's example—and Mr. Gair's—Public Authorities in other parts are taking up this matter as never before."—*The North Star and Farmers Chronicle*. (Dingwall).

OBITUARY

WALTER HENRY KEMP, M.R.C.V.S. Vet.-Maj. late A.V.D., Graduated, Lond: Dec., 1869.

Maj. Kemp died on Aug. 2nd, at Mussooree, India.

JAMES TAYLOR, M.R.C.V.S., Wix, Manningtree, Essex. Lond: April, 1864.

Death occurred on Aug. 30th, from arterio-sclerosis. Aged 70 years.

JOHN YOUNG, M.R.C.V.S., East Calder, Edinburgh. 1870, Edin: Jan., 1880.

Death took place on Aug. 31st, from carcinoma of the stomach, at the age of 66 years.

Original articles and reports should be written on one side of the paper only and authenticated by the names and addresses of writers, not necessarily for publication.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1314.

SEPTEMBER 13, 1913

VOL. XXVI.

COMPULSORY NOTIFICATION.

The discussion of the Tuberculosis Order by the Midland Counties V.M.A., the report of which we publish this week, contains some unexpectedly hostile references to the compulsory notification of scheduled disease by veterinary surgeons. The smallness of the sum paid for notification, and the possibility of offending clients by notifying, were the objections adduced. Neither is sufficient excuse for contravening an Order of the Board of Agriculture which has now been in force unchallenged for more than three years, and the principle of which has been supported by the profession for a very much longer period.

Our own history in connection with compulsory notification should be remembered. It is now nearly twenty years since the profession was circularised upon the question, and a large majority decided in favour of compulsory notification with a fee attached. The decision was not acted upon for many years, but the opinion of the profession did not change; and the establishment of compulsory notification in 1910 passed almost without comment.

The legislation compelling notification places the veterinary practitioner on the same footing as the medical man with regard to scheduled disease. It does not enjoin him to search the premises he may visit for evidence of disease. It does require him, when he is employed to examine an animal which he believes or suspects to be suffering from a scheduled disease, to notify the fact to the proper authority. The fee is small, but it is not the only fee which the examination yields, and it suffices for the slight trouble of notification—most men will admit this. Probably the real root of any present objection to compulsory notification is the fear of offending clients, but the importance of this point may easily be exaggerated. Few clients will find fault with a practitioner for notifying disease if the law relating to it is clearly explained to them, and it is to the interest of our clients and of the community that this should be done. Before the days of compulsory notification, our position with regard to scheduled disease was difficult. We were not obliged to report—we might even have been actionable for breach of confidence if we did report—and so we were often compelled to see the law evaded. The legislation obliging us to notify released us from that unenviable position, and enables every practitioner to do his duty to the State.

ABOUT CONGRESSES.

We have given space this week to some notes about Congresses, because they are sent by an old contributor—one of our earliest, and because we think that his argument is valid—that no such Congress as the one to be held in England next year has ever been held here before, and that few of our members—probably not more than 20, have attended the others of the series held on the Continent. Consequently the majority of our members have little idea of the scale on which such functions are carried out, nor, generally, of the scope of the meetings for which they have so frequently been asked to contribute the “sinews of war,” in order to do honour to their guests, and in so doing to honour themselves.

ENTROPIUM SPASTICUM IN A HORSE.

Becker records (*Zeitschr. f. Veterinark.*) the case of an officer's horse, eighteen years old, which he treated; in the first place for a violent conjunctivitis and keratitis. After a fortnight's treatment the case had improved; and then suddenly a relapse set in. The conjunctivitis and keratitis were now more severe than at the beginning of the illness; and, in addition, an entropium appeared. Recovery could now only be gained by the entropium operation.

After the most severe inflammatory symptoms had been subdued, Becker performed the operation upon the standing horse, under local anaesthesia with cocaine and adrenalin. The skin of the upper eyelid was taken up into a high fold, and adjusted so as to bring the edge of the lid into its proper position. The fold was then removed with scissors, leaving an elliptical cutaneous wound, with a breadth of seven millimetres (= 7-25th inch) between the edge of the wound and that of the eyelid. The skin was then sutured and several layers of gauze and a bandage applied to the eyelid.

Upon the fourth day, however, it became evident that the entropium was only partially overcome; and a second operation was therefore undertaken on the eighth day. This time the fold of skin was drawn so high that the edge of the upper eyelid was slightly everted, thus constituting a slight ectropium. In other respects the operation was carried out as the first one had been.

The next day the ectropium had become more marked, and it was feared that too much skin might have been removed. This fear was groundless. The operation resulted in the complete re-

removal of the entropion; and the conjunctivitis and keratitis also gradually disappeared.

Becker explains the origin of the entropion as follows: The horse suffered repeatedly from a catarrhal conjunctivitis associated with irritation, and sought to relieve the irritation by rubbing against the manger and protruding the third eyelid. In consequence of this the eyeball was drawn back in the orbit by contraction of the retractor bulbi muscle, and the action of the levator muscle of the upper eyelid thereupon drew the edge of the lid inwards.

Becker considers that, in performing the entropion operation upon the horse, the piece of skin removed should be so large that a slight ectropion appears after the operation.—*Münchener Tier. Woch.*

CONGENITAL ATRESIA OF THE LACHRYMAL CANAL.

Hartog records (*Tydschr. v. Vecartsenijkunde*) the case of a colt a year and a half old. The animal had been bought six months before; and, from the moment of purchase, had shown symptoms of conjunctivitis which did not yield to the ordinary methods of treatment.

Upon examination, Hartog found the conjunctiva injected and engorged. The conjunctival secretion was muco-purulent; and the discharge had produced a large erosion of the skin over which it flowed. The cornea was normal, as were also the other component parts of the eye.

Examination of the nasal cavity corresponding to the affected eye showed that the orifice of the lachrymal canal was not present, and that, at the place where it should have been, the mucous membrane was slightly raised. The case was therefore one of congenital obstruction of the orifice of the lachrymal canal.

Hartog examined a piece of mucous membrane at the raised point; and this was immediately followed by the escape of a certain quantity of muco-purulent matter. The conjunctivitis was then treated with a collyrium of nitrate of silver. The orifice established by the excision of mucous membrane remained pervious; and the cure was soon complete.—(*Annales de Méd. Vét.*)

SUGAR IN THE TREATMENT OF WOUNDS.

The antiseptic action of sugar has long been known; and the treatment of wounds by it is also nothing new. Dr. G. Magnus, of Norburg, describes (*Münchener Mediz. Woch.*) his experiments and observations upon the latter question. In the first place, he bacteriologically examined commercial beet-sugar, and found that in no single instance could pathogenic bacteria be demonstrated in it. He then used beet-sugar without further preparation in the treatment of wounds, employing it in about 100 cases.

Magnus found that, in tuberculous processes, a distinct cleansing of the surfaces of the wound certainly appeared; but the specific process itself remained unaltered. Apart from tuberculosis, he considers the results of wound-treatment by sugar encouraging. The sugar acts as a disinfectant and antiseptic. It dissolves fibrin, and stimulates

secretion by vigorous osmotic processes, which are comparable to a rinsing out of the wound with serum from within outwards.

Speedy cleansing, deodourisation, healthy granulation, and rapid proliferation of epithelium result from this. Magnus therefore concludes that sugar is a safe, cheap, and for practical purposes sterile agent.—(*Berliner Tier. Woch.*)

THE TOXICITY OF BORIC ACID POWDER.

Charmoy has published (*Recueil d'Alfort*) an article upon this question. Having been struck by certain symptoms of poisoning he observed in dogs which had been treated with boric acid powder applied to wounds, he studied the action of the drug systematically. After detailing his observations, he states his conclusions as follows:

1. Boric acid powder, used as an external medicament upon the wounds of dogs, is toxic in a dose varying between $2\frac{1}{2}$ to 3 grammes (roughly about 38 to 46 grains) to every kilogramme (2.2lb.) of the animal's weight, provided the animal is in a satisfactory condition of health.

2. The toxicity of the drug is much higher in animals already affected with a chronic disease, especially nephritis or skin disease,

3. The symptoms of poisoning at first are weakness, difficulty in progression, and a slight acceleration of the grand functions of the body. These are followed by vomiting, diarrhoea, and fall of the temperature. Towards the end there is an absolute "muscular resolution," with sometimes the appearance of blood in the excrements and in the vomited material. Death takes place in coma and hypothermia.

4. Death seems to be due partly to the rapid evolution of an acute nephritis, and partly to nervo-muscular paralysis, the latter no doubt being caused by the inhibitory action of the boric acid upon the nerve centres. The author concludes, then, that boric acid is not an inoffensive substance the dose of which is unimportant, and that its use should not be generalised. He suggests that the drug might well be banished from canine therapeutics, and reserved for dressing the wounds of the large animals. Even in the latter it should always be remembered that boric acid has a debilitating and cachectising action, and a manifest tendency to alter the renal apparatus.—(*La Semaine Vét.*)

HÆMORRHAGE FROM THE VENA CAVA CAUSED BY AN EXOSTOSIS OF THE VERTEBRAL COLUMN.

Lagaillarde records (*Revue Vétérinaire*) the case of a mare which, after having leaped the bar in the riding school, galloped a few yards and then suddenly fell. She rose, staggered for the first steps after rising, and then regained her normal appearance.

The next day she was led at a trot with the object of ascertaining if lameness existed; and, at the end of the run, she was turned shortly. She immediately faltered, managed to travel a few yards further, and then collapsed. Four hours later, she died with all the signs of internal hæmorrhage.

The post-mortem examination was exceedingly interesting. The abdominal cavity was found filled with blood. The vena cava, which showed a voluminous thrombus, also presented a large rupture with jagged edges, the rupture being opposite to an exostosis of the vertebral column. The aorta was pushed from its normal position by exostoses of the bodies of the dorsal and lumbar vertebrae, and was therefore sinuous in its course.

The ankylosing osteitis had transformed the thoracic and lumbar regions of the spine into a rigid arc, by ossification of the cartilages and "soldering" of the vertebral bodies. The bodies of the vertebrae were deformed. A great number of them showed osseous formations either upon the lateral parts or upon the median crest. The last lumbar vertebra, upon the right part of its body, exactly opposite to the vena cava, showed a projecting exostosis which was triangular in shape and possessed cutting edges.

As the animal was an Army horse, it was possible to obtain her medical history. Her infirmity record was very small, comprising an incapacity of short duration on account of an exostosis on the internal aspect of the hock, a pharyngeal strangles, and an attack of horse-pox. The gross lesions of the vertebral column had never been suspected during life, only very slight symptoms having been seen which may be attributed to them. At the most these symptoms had been confined to slight resistance to being mounted, and a certain amount of stiffness during the first steps of progression.

This mare resembled many other osteitic patients in having previously been affected with microbial diseases. There may perhaps have been a relation of cause and effect between the microbial diseases and the essentially chronic osteitic process.—*Annales de Méd. Vét.*)

Neither the age of the mare, nor the time which had elapsed since the previous attacks of disease, is stated.—*Transl.*]

W. R. C.

ECONOMIC FACTORS IN CATTLE FEEDING. — II, ARGENTINA AS A FACTOR IN INTERNATIONAL BEEF TRADE.—H. W. MUMFORD (*Illinois Sta. Circ.* 164, pp. 3-18, figs. 10).

This bulletin discusses the present and the possible future of the beef industry in Argentina, which is now supplying European markets with beef formerly obtained from the United States.

The five provinces of Buenos Aires, Corrientes, Entre Rios, Santa Fe, and Cordoba, known as the pampas grass region, contain over 80 per cent. of the cattle in Argentina. Approximately 5,000,000 cattle were slaughtered in 1911, of which about 1,000,000 were shipped abroad as dressed beef, and a considerable proportion of the remainder was prepared for export in other forms. The exports of beef have increased from 64,000,000 lb. in 1885, to 580,000,000 lb. in 1910. Argentine grass-fed beef sells on the English market within from two to five cents per pound of corn-fed beef from the United States.

Expansion of the cattle raising industry in Argentina has ceased, however, largely because grain growing has proved more profitable, and as the cost of beef production will increase with increased cost of labour and land, it is thought that on the whole the business of raising beef cattle in the United States will not be permanently menaced by Argentine competition. A bibliography is appended.

RESEARCHES ON EPIZOOTIC LYMPHANGITIS IN ALGERIA.—J. BRIDRE, L. NEGRE, G. TROUETTE (*Ann. Inst. Pasteur*, 26 (1912), No. 9, pp. 701-726, pl. 1, fig. 1).

Clinical observations and experimental investigations show that the epizootic lymphangitis is transmissible by direct inoculation, and that the intervention of blood-sucking insects is not necessary. A study of new lesions shows that the cryptococcus of Rivolta is not a parasite of the leucocytes. Its morphology and mode of reproduction would indicate it to be of the nature of a blastomycete as do complement fixation tests of the cryptococcus and certain yeasts. The authors find that salvarsan can be used to advantage in treatment of the disease, a 1-grm. dose giving better results than larger doses.

THE WIDTH OF THE JAW OF CATTLE IN RELATION TO MILK PRODUCTION AND THE WEIGHT OF THE HEART AND LUNGS.—G. KORRENG. (*Jahrb. Wiss. u. Prakt. Tierzucht*, 7 (1912), pp. 132-142).

As a result of measurements of calves, bulls and cows, it is concluded that a narrow jaw in cows is associated with a high milk production, and a wide jaw with heavy heart and lungs. The weight of the heart was relatively larger in males than in females, and that of the lungs larger in females than in males.

F. E. P.

ABOUT CONGRESSES.

"There are a good many scientific workers who do not hesitate to declare their belief that Congresses of all sorts are a waste of time and money. They say that nothing new is disclosed—or very seldom, at any rate—and that the 'windbags' and self-advertisers use such meetings as opportunities for taking unto themselves credit which should go to the genuine research worker, whose brains are picked by men merely out for popular applause. There is a certain element of truth in this generalisation; but to the recent International Congress in London it most decidedly does not apply. Not only from a popular point of view, but also from that of strict medical science, the right men were chosen for the big occasions; and the tremendous public interest which has been aroused merely reflects the excellent organisation of the Congress and the discretion of the Committee which took it in hand."

[May not the public press be credited with the greater amount of the "public interest" exhibited—at any rate on the popular side?]

"It would be idle, however, to pretend that every speaker in every section contributed usefully to the proceedings; or that the advertising pseudo-scientist was completely suppressed. But this not alter the fact that the opportunities of this type of medical man were firmly, yet tactfully, curtailed as much as possible; and that in general an extraordinarily high level of scientific medicine was maintained. Again, it is true that very few new facts emerged, and that the great majority of the 'reporters' of the twenty-six sections and sub-sections merely recapitulated the researches and advances of the last few years. But this very repetition, irritating as it may be to the specialist who is fully up-to-date in his own subject and mainly anxious for fresh worlds to be conquered, really constitutes a valuable feature of an International Congress. For by this means the general practitioner, and the specialist, too, have a chance of taking stock of progress, of interchanging views with men of other nationalities, and of surveying the field preparatory to fresh campaigns against disease. Taking a broad view . . . the Congress was an unprecedented success, not only from the point of view of the doctors, both scientifically and socially, but was equally momentous from that of the general community, whose members . . . saw at least enough to interest them profoundly as onlookers with a personal stake in the issues."

So says a contemporary, *The Hospital*. It was not a long step from these remarks to the thought of our Congress of next year, with its similarities and its differences. Perhaps the differences appealed to me more strongly. The Medical Register carried, a year or two ago, nearly 40,000 names. *The British Medical Journal* advertises its issue of Sept. 6th as 30,000 copies. Doubtless a good proportion of these totals apply to men practising out of Britain; the proportion in the veterinary profession is about one-eighth. Assuming that one-sixth of their total are unavailable, there remains over 30,000. The estimated number of guests to the Congress was put at 8000, so that the proportion of guests is just about one-fourth. Now our figures, deducting one-eighth, are roughly 2980, and our guests are estimated at 1200—a proportion not greatly less than one-half.

The fact that the British Government is far less liberal than continental governments towards the profession needs no advertisement. The deduction is inevitable.

Looking now to the popular estimation of the two professions, we may, perhaps, be relatively as well treated by the public press, which did so much for the recent Congress; but consider the divergence of interests. Every man and woman in the British Isles is interested, directly or indirectly, in the practice of medicine. Those who are happy enough not to have interviewed a doctor in their adult life, have wives, children, relatives, friends, some of whom are inevitably less fortunate. What is our case? It is unthinkable that the medical professional could lose in a few years the proportion of patients that were wiped off our books by the reduction of the horse as a tractor. True we have

"breed" animals left to us, and the number of dogs, cats, parrots, and canaries for which our clients have some personal feeling are not diminishing; and there is a larger proportion of the agricultural community who acknowledge the value of our services. But, accepting all these—and the small-holder—what proportion of the whole community acknowledges our services even in Public Health measures, or cares a "tinker's anathema" for us or our work?

Turning to the social side, I am sending a list of entertainments as given in *The Lancet*. They—the medicos—like ourselves, have little to thank the State for in that way; but consider the assistance they received on all hands.

"The council and staff of the London (Royal Free Hospital) School of Medicine for Women entertained at the medical school, Hunter Street, Brunswick Square, a large party of foreign and colonial delegates attending the International Medical Congress at luncheon on August 7th. . . . The medical school laboratories were open to visitors, who were also shown over the Royal Free Hospital and the New Hospital for Women."

"On Thursday, August 7th, Sir Alfred Pearce Gould, Dean of the Faculty of Medicine of the University of London, and Lady Pearce Gould gave a garden party at the College, Regent's Park, at which a very large number of the members of the Congress were present."

"The dinner given by the Society of Apothecaries of London on Thursday, August 7th, fully sustained the world-wide reputation of the City Companies for excellence in the science of hospitality and in the artistry of dining. The guests were received by the Master, Mr. W. Bramley Taylor, and the Wardens, Mr. Martindale Ward and Mr. Meredith Townsend."

"On Thursday evening, August 7th, the President and Council of the Royal College of Surgeons of England entertained a large company at a soirée in the College. The guests were received by the President, Sir Rickman J. Godlee, and the Vice-Presidents, Mr. G. H. Makins and Sir Frederic Eve, in the Inner Hall. In the Conservator's Office an interesting collection of microscopical preparations from 1780 to 1812 was on view, and in Rooms VII. and VIII. of the Museum there was an exhibition of historical and anthropological specimens, while Hunterian relics and other objects of much interest were shown in the Council Room."

"The conversazione at the Royal Army Medical College, Grosvenor Road, S.W., on Thursday, August 7th, was a brilliant function, attended during the course of the evening by some 800 people. Surgeon-General Sir Lancelot Gubbins, Director-General, A.M.S., and Lady Gubbins received the guests, who, after partaking of refreshments, were permitted to thoroughly inspect the College, where many striking exhibits were on view, comprising service rations of various armies, with demonstrations of the damage by insects to which they are subject, demonstrations of X ray and high-frequency electricity, methods of water purification and food analysis, clothing and equipment, demonstrations of various tropical diseases and microscopical specimens, field medical and surgical equipment, and so forth. A feature that attracted considerable attention was a cinematograph display of trypanosomes, amoebæ, bacteria, and spirochætæ."

"On Friday evening, August 8th, the Corporation of London gave a magnificent conversazione at the Guildhall to welcome the members of the Congress. The entertainment, which was worthy of the City's reputation for hospitality, had been organised on a very large scale by a special reception committee of the Corporation under the chairmanship of Mr. H. H. Wells. The Lord Mayor, the Right Hon. Sir David Burnett, accompanied by the Sheriffs of the City of London, received the guests in the Guildhall. The spectacle in the Library, Art Gallery, Council Chamber,

and Guildhall was a very brilliant one. Concerts and entertainments were given in the various rooms open for the reception, and there was dancing from 9 o'clock in the Library. In the Guildhall a selection of the Corporation plate from the Mansion House was displayed, and the museum and collection of ancient clocks and watches belonging to the Clockmakers' Company were also open for inspection. An additional delight for those to whom the City's treasures are unfamiliar was the exhibition of the ancient charters granted to the City of London by William I., Henry II., Richard I., and John, and the collection of manuscripts, medals, coins, and badges dating from the thirteenth century."

"A special feature of the entertainments of the Congress was the garden party at Windsor Castle at the invitation of the King on Saturday, August 9th. The invitations were perforce limited to 2000, but it was found that the applicants would very greatly exceed those for whom it would be possible to make adequate provision. Some half-dozen special trains, at intervals of a few minutes, was run between 2 and 3 p.m. from the Great Western Station at Paddington direct to Windsor for a return fare of 2s. On arrival at the Castle the King's guests were received at the grand entrance by the Lord Chamberlain on behalf of His Majesty, the Comptroller of the Household, the Deputy Master of the Household, the Surveyor of the King's Pictures (Mr. Lionel Cust), the Keeper of the King's Armoury (Mr. Guy Laking), and the Inspector of the Palace (Mr. G. E. Miles). . . . Passing on to the East Lawn, this magnificent pleasure attracted universal admiration. In large marquees an elaborate tea, with champagne, ices, and abundant delicacies, was provided, the tables being decorated with flowers from the Royal gardens. The spectacle was one of extraordinary vivacity, presenting the most democratic assemblage that has ever occupied that lawn."

"A delightfully intimate and admirably managed excursion was the river party on Sunday, August 10th, on the invitation of the President (Dr. Reginald Morton), officers, and members of the Section of Electro-therapeutics of the Royal Society of Medicine. The guests to the number of 100 embarked on the launch "Royalty" at Westminster Pier at 10.30 a.m., and proceeded up the river, calling at Richmond to take on a few who had failed to catch the boat at Westminster. . . . Sir James Mackenzie-Davidson, President of the Section of Radiology of the Congress, was present. The day was fine, and the genial care of Dr. Reginald Morton and Mr. Archibald Reid, the chief organising spirits, charmingly seconded by Mrs. Morton and Mrs. Reid, for the comfort of their guests was greatly appreciated by all. An excellent luncheon was served. On the homeward journey afternoon tea was served. The party reached Westminster pier about 7.30."

"On Monday morning, August 11th, a deputation of the French members of Congress were met at the Royal College of Surgeons of England by the President, Sir Rickman Godlee, when they placed a wreath beneath the bust of Lister, newly executed by Sir Thomas Brock. . . . They afterwards looked at a collection of Lister's manuscripts, drawings, and instruments, which had been prepared for their inspection."

"At the session on Monday, August 11th, of the Section of Tropical Medicine and Hygiene, Professor Blanchard presented a large gold medallion to Sir Patrick Manson, as an acknowledgment from France of the value of his work in the prevention of malaria. The medallion bears on it a portrait of Sir Patrick Manson, and is the work of M. J. Richet."

"Sir Thomas Barlow, as President of the Congress, gave a dinner on Monday night, August 11th, at the Savoy Hotel, at which some 200 foreign and British members of the Congress and distinguished guests were entertained. Among those, in addition to the delegates from foreign Governments and the presidents of the different sections, and the officers of the Congress, may be mentioned the Archbishop of Canterbury, the Cardinal Archbishop of Westminster, the Dean of St. Paul's, the American Ambassador, the Lord Mayor of London, Lord Haldane, Mr. John Burns,

Mr. McKenna, Mr. Sydney Buxton, Sir Archibald Geikie, Sir George Reid, Professor Ehrlich, Professor Harvey Cushing, Professor Chauffard, Lord Strathcona, Professor W. Bateson, Sir Rickman Godlee, Sir T. Clifford Allbutt, and Sir William Osler. The dinner was quite informal, and there was no toast list. . . . During dinner the Westminster Singers delighted the audience with their admirable rendering of old British songs."

"At the *Conversazione* given by Lord and Lady Strathcona to the members of the Congress on August 11th, the night was fine and the Botanical Gardens glowed with myriads of fairy lamps, outlining shrubberies and trees and flower beds. . . . The Royal Artillery Band and the Prince's Red Band added the charm of music; pipers from the Scots Guards played and danced; while the Folk Song Quartet rendered a selection of Ballads. Lord and Lady Strathcona themselves received their guests, who approached, for lack of space, in a sinuous queue. Approximately 5000 persons were present. It was a charming *fête*."

"Under the banner of the Æsculapius Lodge, No. 2410, and supported by the Rahere, the Cavendish, the Sancta Maria, the Middlesex Hospital, the London Hospital, La Chère Reine, the King's College Hospital, and the Lanesborough Lodges, a meeting of medical Freemasons in connexion with the International Congress of Medicine took place at Freemasons' Hall on Monday afternoon, when nearly 300 members of the craft were present, including a large number of foreign and colonial brethren. A lodge was opened by the W.M. (Dr. A. P. Beddard) and the officers of the Æsculapius Lodge, and later the Pro-Grand Master of England Lord Amptill, occupied the chair. Mr. Edmund Owen, P.G.D., and Mr. Ernest Clarke, P.G.D., acting as S.W. and J.W. respectively. . . . Tea and coffee were served from 3.30 till 4.30, and the arrangements for the meeting were admirably organised by Dr. J. R. Probyn-Williams, P.G.D."

We, a young profession, have have had to make our way. Ignored by the State almost entirely up to 1866, and not much better treated in the following years, we have had to stand "on our own." No reasonable man can deny that we have stood up to what was in front of us, and we are not ashamed of our record. But that has not surrounded us with a host of wealthy friends nor attracted the attention of Royalty. We are "on our own" still. We have friends—good friends—but they are few. We have men amongst us who can, and have, stood forward in this matter of the International Congress: but has it not been left to too few? At a meeting of one of our local societies a few weeks back, the Secretary reported that 40 of the members to whom he had applied *had failed to reply at all*. It has to be admitted that there are amongst us members who, at most, could only afford a few shillings, but these do not form a numerous section, and to each and every man who has not subscribed I would say as they say in Devonshire, "Du zummut, du gude ef you can, du zummut!"

SOUTH COUNTRY.

MIDLAND COUNTIES VETERINARY MEDICAL ASSOCIATION.

The quarterly meeting was held at the Grand Hotel, Birmingham, on Wednesday, August 20th, the President, Mr. J. Martin, of Wellington, occupying the chair. There were also present Messrs. Brennan DeVine, L. C. Tipper, S. Woodward, Birmingham; J. J. Burchall, Barrow-on-Soar; W. H. Brooke, Handsworth; H. L. Pemberton, Bridgnorth; W. S. Carlless, Worcester; R. Over, A. Over, Rugby; R. C. Trigger, Newcastle-under-Lyne; H. Collett, West Bromwich; R. Murray, Ruge-

ley; Thompson, Stafford; D. Forwell, Towcester; T. Chambers, Dudley; L. W. Heelis, Solihull; W. E. Ison, Atherstone; W. C. Clifford, Shifnall; T. Whyte, Tenbury; T. Slipper, Sutton Coldfield; W. Grasby, Davenry; and the Hon. Sec., Mr. H. J. Dawes, of West Bromwich.

Two visitors were welcomed, namely, Messrs. W. D. Connachie and W. White, Birmingham.

Apologies for unavoidable absence were announced from Profs. Hobday and Dewar, and Messrs. C. E. Dayus, Parsons, Ringer, W. H. Brown (Northampton), J. Martin, jun., F. L. Gooch, T. L. Hobson, J. P. Carless, W. T. Wilson, T. J. Brain, R. Clunas, T. Bainbridge, R. McGregor, R. Cockburn, F. H. Gibbings, J. W. Coe, A. B. Forsyth, E. Woodcock, J. Duckworth, T. J. Prince, R. Hughes, F. W. Barling, John Blakeway, H. S. Reynolds, H. Yeomans, and others.

The Hon. Sec. read the minutes of the previous meeting, which were confirmed.

New Members.—The following gentlemen, duly nominated at the previous meeting, were now elected members of the Association:

Prof. W. T. WILSON, Harper Adams College, Newport, Salop, proposed by Mr. Pemberton, seconded by Mr. Clifford.

Mr. R. CLUNAS, Hodnet, Salop, proposed by the Hon. Sec., and seconded by Mr. Carless; and

Mr. J. MARTIN, JUN., Newport, Salop, proposed by Mr. Clifford, and seconded by Mr. Pemberton.

Mr. EDWIN HALL, of Wellington, was nominated by the President, and his name will be submitted for election at the next meeting.

Resignations.—The Hon. Sec. reported that Mr. F. J. Taylor, formerly of Moseley, and now of London, had tendered his resignation on account of his leaving the district. They were all sorry, he was sure, to lose Mr. Taylor, who had served the office of President of the Association, and had always taken the keenest interest in its welfare. He moved that it be accepted with regret. This was seconded by the President, who said they could ill afford to lose such enterprising members. The resolution was carried.

The Hon. Sec. also announced the resignation of Mr. James Blakeway, and this was also accepted with regret.

RECOMMENDATIONS BY THE COUNCIL.

The Hon. Sec. reported that a meeting of the Council of the Association had been held just prior to this meeting, when there were present Mr. Martin in the chair, Messrs. Carless, Grasby, Pemberton, DeVine, Ison, Trigger, R. Over, Brooke, Burchnall, and the Hon. Sec. The following recommendations to the general meeting were made:

1. That Northampton be the next place of meeting.
2. That Mr. Noel Pillers, of Liverpool, be invited to read his promised paper on "Mange."
3. That at the annual meeting at Birmingham next February, Prof. Reynolds, of the Royal Veterinary College, be requested to read a paper with demonstrations on "Canine Surgery," Mr. Grasby kindly undertaking to make the necessary arrangements; and
4. That the affiliation fee of 1s. per member due from this Association to the National Veterinary Medical Association be paid forthwith.

The Hon. Sec. reported to the Council that he had received further promises towards the fund in connection with the forthcoming visit of the International Veterinary Congress to London. He regretted to say that 40 members had failed to reply to his circular one way or the other, which he considered scarcely satisfactory.

On the motion of Mr. R. Over, seconded by Mr. Tipper, the above report was accepted, and the recommendations contained therein were agreed to.

THE INTERNATIONAL CONGRESS.

Arising out of the report of the Council, the Hon. Sec. referred to the question of the Guarantee Fund to meet the expenses of entertaining the International Veterinary Congress in London next year. In other countries the Government made a handsome grant towards the expenses, and even entertained the delegates on a generous scale, but they would not get that in England, and it was left to the profession to see that their distinguished guests were properly treated. When they remembered how well the medical profession entertained the delegates to the International Medical Congress only last week, he thought it would not be creditable to the veterinary profession if visitors from abroad were not treated as well as English delegates had been at Congresses elsewhere. There were members who had not yet replied to his circular who he thought would give something, and he made one last appeal to them to associate themselves with the present movement.

Some discussion took place on the best means of reaching those members who have not already subscribed, and the Hon. Sec. said that Sir Stewart Stockman had asked him for a list of all who had not subscribed, with the intention of making a personal appeal to them for assistance before the Fund closed.

THE ROYAL SANITARY INSTITUTE CONGRESS.

The President, who represented the Association at the Congress of the Royal Sanitary Institute at Exeter in July last, reported briefly upon it. He said they must regard with steadily increasing satisfaction the importance which the public were beginning to attach to the veterinary profession in matters pertaining to the public health. He attended the discussions on five papers, all of which were of interest to the veterinary surgeon. He enjoyed his experience very much indeed, and he thanked the Association for giving him the opportunity of attending the Congress.

On the motion of Mr. Trigger, seconded by Mr. Ison, a hearty vote of thanks to the President for representing the Association on the occasion in question.

A COMPLIMENT TO THE HON. SEC.

Mr. TRIGGER said they owed so much to Mr. Dawes, who had been hon. secretary of the Association for twenty years or more, that when they had a chance of paying him a small compliment they ought not to let it pass. As most of them knew, his son, Mr. Howard Dawes, had just come through his college course with flying colours, and in practically every branch of veterinary study had carried everything before him. Mr. Dawes, senr., must naturally be very proud of such a son, and he moved that the congratulations of the Association be tendered to Mr. and Mrs. Dawes upon this happy result.

Mr. Ison said that as one who had been privileged to examine Mr. Dawes, junr., he would like to second the resolution. Mr. Howard Dawes was looked upon by his professors as one of the most brilliant students who had passed through the college for many years.

The resolution was carried by acclamation, and Mr. Dawes, in acknowledgment, said he very much appreciated the recognition of his son's success which the Association had made. He hoped his son would become a member of the Association, and that he would take as much interest in its affairs as he himself had done.

SPECIMENS.

Mr. TRIGGER, on behalf of Mr. Coe, who was unable to attend, produced the larynx of a horse which had been slaughtered within the past day or two. The larynx was entirely flat, and it was believed to be the result of an accident, the animal having at one time run into a gate and injured itself.

Several members criticised this explanation of the condition of the larynx, and held the view that it was congenital and not due to an accident at all. Mr. Trigger said that was his own opinion.

Mr. R. OVER exhibited a case of a verminous aneurism in the mesenteric artery. The animal was a thoroughbred foal, which was taken bad a few days ago. It looked a bit dull at first, and was lame in the off-fore leg. The lameness then disappeared from the fore leg and passed into the off-hind leg. The post-mortem showed a certain amount of peritonitis, and there were spots on the bowel with abscesses forming. The kidneys were very enlarged and contained minute abscesses.

Mr. PEMBERTON showed a number of calculi of abnormal size and shape which were removed from a horse by the hand, with good results.

THE TUBERCULOSIS ORDER, 1913.

By BRENNAN DEVINE, F.R.C.V.S., D.V.S.M.,
City Veterinary Dept., Birmingham.

The Tuberculosis Order of 1913 has been so much discussed by the veterinary profession during the past three months that it is difficult to introduce anything new about it, or to bring forward any remarks for discussion which you have not already thoroughly thrashed out. The Order, as you are all aware, came into force on May 1st last. Under this Order clinical tuberculosis of all bovines is compulsorily notifiable. The Order was designed to organise a method of eradication of the more badly infected tuberculous cattle and thereby remove the worst centres of infection from our herds, as well as to reduce the chances of infection to human beings through the milk and meat.

Notification. As regards notification of the disease, the onus should necessarily fall on the owner of the animal, but if a veterinary surgeon meets with a suspected case of tuberculosis in a bovine in his daily practice or otherwise, it is his duty to report it to the local authority. Under the Notification of Diseases Order, the veterinary surgeon is entitled to a fee of 2/6 for each outbreak reported; of course, if the local authorities wish they may increase this fee. I feel sure none of us object to reporting cases of any of the scheduled diseases—every veterinary surgeon nowadays recognises it as his duty to do everything possible to arrest and prevent disease. This may seem a cut-throat policy, and against one's own interests, as eventually all disease may be cleared out and there may be little work left for the veterinary surgeon; notably, Pleuro-pneumonia, Foot-and-mouth disease, Glanders, and Rabies, have virtually been extirpated. But the great tendency, in fact I may say the bounden duty of the members of our profession at the present day, is to concentrate one's aim on prophylactic measures and to carry them out where possible. In addition to reporting suspected cases to the local authority, the veterinary surgeon should also point out to the owner the many advantages to be derived by ridding his herd of those bad centres of infection—the visible clinical cases, and thereby dispensing with further inspection. The veterinary surgeon can do much real good towards eradicating the disease by instructing the owners in the risks they run by keeping infected animals, or by introducing new animals into their herds without having them previously tested. I know of several instances of herds which I have tested in Birmingham and district where but one apparently affected animal has infected several in the same shed during the comparatively short period of six months. Although we cannot hope to clear tuberculosis from our sheds under the present Order, yet we all recognise it is a step in the right direction, and if local

authorities efficiently carry out the provisions of this Order the percentage of affected animals must necessarily be considerably reduced, and this, of course, will reduce the risk of infection to human beings.

It would perhaps be premature for me to suggest here that all milking herds should be tested with tuberculin, and that all the re-acting cows should be kept barren and fattened off. All of us who have carried out testing with a view to obtaining a tubercle-free herd look on the present Order as only partial and temporary. We have all seen apparently healthy, good-looking, well nourished cows react to the tuberculin test, and if allowed to continue in a herd they affect many others within a short period. At the same time I think it is not unlikely that in the near future some system of testing the milking herds will be taken up by the State, and until some such system is carried out we cannot hope to exterminate tuberculosis from our herds.

Inspection and Examination. The section of the Order dealing with inspection and examination of animals is, from the point of view of the veterinary surgeon, a very important one. The local authority is there instructed to cause a veterinary examination to be made of all suspected cases reported. Though this Order applies to the whole country alike, as other Orders under the Contagious Diseases (Animals) Act, I am inclined to believe that the necessity for its application has not been properly appreciated alike by all the public bodies concerned, or rather, that its meaning has not been equally interpreted by them. If public bodies are known to be lax in the carrying out of the provisions of the Order (and I have reason to believe there are many), or if they evade their duty in any way, the matter should be reported to the Board of Agriculture with a view to having it thoroughly investigated.

Under the same section, the veterinary surgeon is empowered to take samples of milk and of faeces, urine, or any other abnormal discharge, for purposes of diagnosis. If tuberculosis of the udder is suspected a sample of milk will naturally be taken for microscopical examination. Tuberculosis of the udder is rarely a primary disease; it is usually secondary to lesions in the thoracic or abdominal cavity, the disease extending to the udder usually through the lymphatics. The affected quarter at first usually shows a swelling without heat or pain. This gradually becomes hard and spreads over the whole quarter. The hardening and enlarging of the quarter is unaccompanied by any inflammatory symptoms. The milk at first remains normal in appearance, but later becomes thin and watery looking. As a rule it is one of the hind quarters that is first attacked and the disease may affect later all the four quarters. The induration usually begins high up, deeply situated in the depth of the quarter. When taking samples from suspected quarters the udder should be cleaned, and the milk should be collected in a sterilised bottle direct from the teat. The milk is taken from the suspected quarter only, and if more than one quarter is suspected separate samples should be taken from each quarter. I have been in the habit of taking stripping from the udder, and I believe one is more likely to find the tubercle bacilli in the last milk drawn than in the fore milk, though I have met with cases in which the fore, middle, and last milk was found to contain tubercle bacilli. The milk should be examined as soon as possible after collection; if the milk is to be kept for any length of time before being examined it should, immediately it is extracted from the cow, be cooled down to 48 degrees F. The quantity of milk taken should be, where possible, at least 4 ounces. The milk is then microscopically examined, as follows; it is first centrifugalised. The time taken in this process depends on the power of the centrifugal machine, but with a good powerful machine the milk should be kept

on at least 20 minutes. After centrifugalising the milk, cover glass preparations are made from the sediment and cream. It may be necessary to make several examinations from the same milk, as in the early stages of the disease the bacilli are sparse in number. After the films are made on the cover glasses and fixed by heat they are stained by the Ziehl-Neelson method, counter stained methylene blue and examined under $\frac{1}{2}$ oil immersion lens. As regards the microscopical examination of the faeces as an aid to the diagnosis of tuberculosis in cattle, I do not consider it of much value. Granted one finds acid-fast bacilli on microscopical examination of faeces of cattle, we are no further forward in our diagnosis. The acid-fast bacilli detected may, or may not, be tubercle bacilli, but one cannot give a positive opinion, because so many other acid-fast bacilli are likely to be met with in the faeces of cattle, such as Johne's bacillus, Timothy grass bacillus, etc. As far as I can see, the microscopical examination of faeces alone for the purposes of diagnosis of tuberculosis in cattle has no practical value. Urine is another sample mentioned in this section which may be taken for diagnosis. The examination of the urine is carried out on the same lines as the milk, the urine being previously removed with a sterilised catheter. Whenever you get tuberculosis of the urinary system—of the kidneys, ureter, bladder, etc., it is generally found associated with a generalised tuberculosis, and rarely seen separate. The words "Any abnormal discharge" in the Order give one power to stake a specimen from any of the natural orifices. As far as I am aware the most valuable discharge for diagnostic purposes is one derived from the respiratory apparatus. Such a discharge may be collected in a swab from the pharynx, especially if the animal is made to run some distance to cause coughing. I understand there is an instrument used in Germany for penetrating the trachea and taking specimens of mucus on swabs direct from the bronchi. In advanced cases of pulmonary tuberculosis in cattle the mucus removed from the lining of the bronchi is particularly rich in tubercle bacilli. In examining specimens of mucus, films on cover glasses are used fixed by heat and stained in the same way as the milk sediment. In examining human sputum for phthisical cases the percentage of successful results has been greatly increased by the use of antiformin, which dissolves the animal matter other than the acid-fast bacilli. The method employed is as follows: The sputum is placed in a test tube and a five per cent. solution of antiformin is added. This is then shaken up and allowed to stand half an hour and then centrifugalised; the top fluid is poured off and the top layer of the sediment is examined microscopically. I understand the same method is now successfully employed in the microscopical examination of milk samples.

Under the same section of the Order, provided the Inspector has the written consent of the owner, the animal may be tested with tuberculin. The tuberculin test is the only applicable and certain test we have to detect cases of tuberculosis where no positive signs of the disease are apparent. With the tuberculin test we can state definitely within 24 hours whether the animal is affected with tuberculosis or not. The use of tuberculin is harmless, but one must be careful in applying the test to avoid any errors in diagnosis. In most cases when the situation is explained to the owner, there is seldom any difficulty in getting him to acquiesce in having the animal tested. Tuberculin may be used for testing animals in various ways; the ophthalmic, endermic, intradermic, or subcutaneous method may be carried out. I have tried all four systems, the last named being the commonest form, and the one with which I have been most successful. I consider the subcutaneous method of testing with tuberculin thoroughly

reliable, and when properly carried out leaves little room for doubt. In one herd of 36 cows which I tested in December, 1909, the result showed 24 cows were affected and 12 were free. We had here in what was considered a beautiful herd of dairy cows 66 per cent. of tuberculous animals. The cows looked so well that one could not help feeling a little doubtful about the reliability of the test; however, the reactors were separated from the free, and all the affected were gradually cleared out of the herd by being fattened and slaughtered. When ready for slaughter they were killed on the place, and I had an opportunity of making a post-mortem examination on every animal. The result was that the tuberculin test was verified in every case. In the majority of cases tuberculosis was found in the lungs, and in a few in the pharyngeal glands only. I know there are some practitioners who do not place the reliance on the tuberculin test that it deserves. They say a badly affected animal may not react, and that a non-tuberculous animal may. I would advise those people not to use tuberculin out of a bottle which was opened months ago and has since been standing on a sunny shelf in the surgery. The tuberculin should be used fresh and out of a newly opened bottle, the dose injected should be rather over than under, and if there is a suspicion that a cow has recently been tested the temperature should be taken from the second to the 21st hour with a tested thermometer and by a reliable person—not the farmer or his man. By using care in the application of the tuberculin test we can reduce to a minimum the doubtful and erroneous conclusions.

I should not like to pass this part over without saying a word as to the control of the sale of tuberculin. There is no doubt that the broadcast way in which tuberculin is sold by many firms in this country has a good deal to do with the uncertain results obtained. It has its effect on high priced show cattle and on those exported, as they are often injected previously by the owner, and that the manufacture and sale of tuberculin should be State controlled is a necessity becoming more apparent each year.

Post-mortem Examination of Slaughtered Animals.—Under this section of the Order the veterinary surgeon is to make a post-mortem examination of any animal slaughtered under the Order. In the great majority of cases a definite diagnosis can be arrived at without having to make a microscopical examination of the affected parts. The more common seats of tuberculous lesions in affected cattle are in the pharyngeal, mediastinal, and lymphatic glands. The naked eye appearances are so well known that it is not necessary to dwell on them here; suffice it to say that in the early stages you find necrosis, later followed by caseation. The principal lymphatic glands to examine on making a post-mortem under this Order are as follows: Pharyngeal, submaxillary, mesenteric, supramammary, hepatic, renal, cervical, pectoral, suprasternal, suprascapular, iliac, pelvic, and precural. In doubtful cases, when one is not quite sure that the lesions are tuberculous, sections should be made of the suspected parts and examined microscopically.

Cleansing and Disinfection.—Section 12 of this Order is one that has been overlooked a good deal. Under the Board of Agriculture Diseases of Animals (Disinfection) Order of 1906, the following is laid down:

The place or thing or part thereof required to be disinfected shall be thoroughly coated or washed with

(a) A one per cent. (minimum) solution of chloride of lime containing not less than 30 per cent. of available chlorine; or

(b) A five per cent. (minimum) solution of carbolic acid (containing not less than 95 per cent. of actual carbolic acid) followed by a thorough sprinkling of lime wash; or

(c) A disinfectant equal in disinfective efficiency to the above mentioned solution of carbolic acid, followed by a thorough sprinkling with limewash.

In carrying out disinfection following the removal of infected animals, the first and most essential part is to have the place thoroughly cleansed; plenty of water, soda, soap, and brushing, and follow this up with the application of a fluid disinfectant equal in germicidal power to any of the above. A 10 per cent. solution of sulphate of copper is a cheap effective form of disinfection for outbuildings, but it has the disadvantage of corroding metal parts. A 10 per cent. solution of carbolic acid followed by limewash is as convenient a method as any. Under Section 44 of this Order there is an extension of Sections 19, 20, 43, and 44 of the Diseases of Animals Act of 1894. This Section grants to inspectors many powers over those cattle owners who, by hiding stock or otherwise, attempt to evade the law. It is hoped that the local authorities all over the country will effectively carry out the provisions of this Order, and will not hesitate to take advantage of its many facilities of ridding their districts of all those cases of tuberculosis which are affected by this Order.

At the close of the paper, Mr. DeVine submitted specimens under the microscope of tubercle bacilli from milk and of the bacilli of Johne's disease, for which the tubercle bacilli is likely to be mistaken.

DISCUSSION.

Mr. TRIGGER said he had listened to the paper with greater pleasure than he had anticipated, because although he was familiar with the Order, Mr. DeVine had presented the subject in a most attractive form. He thought they must all agree, though he did not take a rosy view of it, that in attacking wasters they were doing a big work in the right direction. The essayist rather staggered him when he said that one apparently healthy cow was proved to have disseminated the disease among a herd in the short space of six months. He did not think local authorities, at least at this stage, wanted to embark on anything very heroic. County Councils had no desire to go beyond absolute diseased animals, and those in an advanced stage of the disease. He hoped that by slaughtering these wasters they would do good, but he did not think it was quite sufficient. Only the previous day he saw a cow in the market, which he ordered out, and she was afterwards sold for £2. She had tuberculous udder, and was in the last stage of the disease. If knackers would give farmers £2 or more, it was no use veterinary surgeons valuing them at 30s., as was generally done. They must value cows a little more highly. They had to give the value of a cow supposing she was tuberculous, and supposing she was not tuberculous, and that was often rather a difficult matter. If the cow was a waster, the veterinary surgeon may lose nothing by sending her to the knacker, but if she turns out not to have been diseased, and he had previously valued her if free from disease at, say £20, he soon got into hot water with the County Council for having her slaughtered. He thought they attached too much importance to the contagious nature of the disease and overlooked other causes of the spread of the disease, he did not mean heredity, but the hygienic and dietetic conditions under which the animal lived. He mentioned a case in which water from a colliery was run through land where cattle drank it. The cattle, which were all right before, became affected, and when the water was diverted from this land the owner gradually got his herd better again. Prof. McCall once told him of a similar case, suggesting that the spread of the disease was caused by the cattle drinking contaminated water. He always found on farms near collieries a lot of what were called wasters.

He did not know what was to be done in the matter of auctions, for as far as he knew very few local authorities had any inspectors of auctions. He took the law into his own hands in the case he had just referred to, but he was met by the statement that the same animal could be taken into other markets and not get stopped.

Mr. DEVINE: Veterinary surgeons should report the matter to the Board of Agriculture when local authorities fail in their duty.

Mr. TRIGGER added that he hoped this Order was the beginning of a new era. It was certainly letting the public know that something was being done in the eradication of a dreadful scourge, and he agreed with Mr. DeVine that in a few years the State would insist on all animals supplying milk to the large towns being tested with tuberculin.

Mr. TIPPER said he was a member of the Executive Committee of an important County Council, and he would like to say in reference to Mr. DeVine's criticism on local authorities for not acting as expeditiously and as energetically as they might, that Mr. DeVine had overlooked the fact that the Board of Agriculture themselves had advised local authorities not to put too much energy into the Order in its early days, and he thought quite rightly too. There were difficulties which they all realised. One result he had went to show that the pessimism that existed about tuberculosis among stock was a little too pronounced, because the returns so far given as to animals slaughtered under the Order were not very considerable. But the point he wanted to bring before the meeting was this: they were aware that the question of compensation had been delayed in this country for years because a basis of compensation could not be arranged. There was the demand on the part of the owners for compensation, and the refusal on the part of the Government to pay compensation, and there had been a sort of half-way arrangement which enabled this Order to be put into operation. It was the absence of a proper basis of compensation which they were suffering from to-day, and if it became known that the administrative expenses were three or four times as great as the amount paid in compensation there would be an outcry from the ratepayers. It was generally understood that half or a third of the money would be found by the Government. In the County of Worcester, where their friend Mr. Carless was one of the inspectors, he found that out of 31 suspected cases reported, 17 were found to be suffering from the disease and 14 were non-tuberculous. Sixteen had been slaughtered and one remained to be slaughtered, the owner having objected. The total amount of compensation paid was £39 17s. 6d., and they had received as salvage £17 8s. 9d. They had a claim on the Board of Agriculture of £11 4s. 4d. The total expenditure by the Committee was £157 8s. 5d., and they received from the Government £11 4s. 4d. They should try to bring pressure on the Board of Agriculture so that the basis of compensation should also include a share of the administration expenses. The highest compensation his committee paid for an animal was £5 5s., and in another case it was £4 10s. As far as the Worcestershire County Council was concerned, they were as advanced as most County Councils in the country, and their inspectors were being increased.

Mr. CARLESS said if a man was an inspector under the Order, he was afraid it was not a fact that he got 2s. 6d. for every case he reported. It was very difficult for a veterinary surgeon to report the case of his own client. If he were to report some of his clients he would soon lose them altogether. With regard to tuberculin, he had used it for testing purposes hundreds of times, and in a herd of 20 he generally got seven or eight that reacted, but it was not always the poorest animals that did so.

Mr. CHAMBERS related his experience of the Order, and said he did not think it was going to answer as at present administered.

Mr. WHYTE asked whether in the case of a suspected cow it would not be better to fatten it during the period of isolation, so as to make it ready for the butcher.

Mr. GRASBY said the instructions issued to them as inspectors as to the method of taking the milk, etc., seemed to be very elaborate, but there were difficulties which a practitioner appreciated better than those who had drawn up the Order. He mentioned a case in his own experience in which milk was being sent to London from a dairy of 36 cows, and on the 20th of June samples were taken at Harrow and examined at the Lister Institute. A month later a report came to the local authority saying evidence of tuberculosis was found in the milk. They went over the herd in the usual way, but it would have been absurd to isolate any one cow. They fixed on three, the others appearing to be perfectly healthy. Specimens of the milk were sent to the Veterinary College in London, and acid fast bacilli were found. The cow that was found to be affected was isolated, but the owner declines to have her slaughtered unless he is paid compensation for her milk until such time as she would have run dry. He threatened to proceed against the local authority for the loss of profit owing to the milk from these three cows not going to London. It was all very tedious work, and there was bound to be a policeman on the ground as well as the sanitary inspector. Such things as that worried clients, and made the Order very unpopular.

Mr. PEMBERTON asked whether testing with tuberculin affected a cow in calf? He tested three cows that were in calf, and two of them slipped their calves. As for reporting cases, he was not going to report tuberculosis at 2s. 6d. a time. It was absurd to think they were going to offend their clients for the sake of half-a-crown. He commented on the absence of properly qualified inspectors from markets.

Mr. SLIPPER said that as far as he knew there was no inspection of the markets in Staffordshire at all.

The PRESIDENT said his thanks were due to Mr. DeVine for his kindness in preparing such an interesting paper that afternoon, and however much they knew the Order, his remarks had given them food for reflection. He mentioned a case in his own practice where water from a colliery was the suspected cause of tuberculosis in cattle. He could endorse what other speakers had said about the inefficient manner in which markets were inspected. He also agreed with those who objected to the present system of compensation. It was not only inadequate, but it was also frequently unfair.

Mr. DEVINE, replying to the discussion, said he felt greatly flattered by the reception given to his paper. With regard to the association of pit water with tuberculosis, he would like to see an analysis of the water before expressing an opinion himself, as he did not see how water coming out of the ground in that way could contain tubercle bacilli. It might, of course, contain some chemical substance which might so lower the animal's power of resistance as to make it more likely to contract tuberculosis. He was interested in Mr. Tipper's figures as to the working of the Order in Worcestershire. Mr. Tipper mentioned that there were not so many cases as had been expected, and then he went on to say that the Board of Agriculture had asked local authorities to "go slow" at first. That being so, the returns which Mr. Tipper quoted could not possibly be taken as any criterion of the number of diseased animals in the country. He agreed that the Government should pay a fair share of the working expenses of the Order, although that was perhaps not a matter for them as veterinary surgeons. Veterinary surgeons had to get their own bread and cheese, but the question of appor-

tioning the cost of administration affected the ratepayers. When they considered the number of people in London who were consuming meat and milk who paid nothing in the way of compensation, the cost of which came on people living in the country districts, they would see at once that it was a national and not a local question. Mr. Carless suggested that a veterinary inspector would not get 2 6 per case he reported outside his work as inspector. If he went out on County Council business, it would be a different matter, but if he met with a case in his ordinary practice and reported it, he would surely be entitled to his fee. As for the difficulty of reporting the case of a client, which more than one speaker had referred to, he wanted to emphasise that it was their duty to explain the matter to clients and advise them that what was done was really in their own interests in the long run. Mr. Whyte had asked whether it would be right to fatten a cow that was in isolation; his own experience was that no good would result, but the owner could try to do so if he wished. In the case mentioned by Mr. Grasby, he did not think the owner had any claim on the local authority for damages. That point had been decided in the case of holding up horses that were suspected of suffering from glanders. In answer to Mr. Pemberton, he did not think it would harm a cow in calf to apply the tuberculin test. If they used the Pasteur tuberculin, he advised them to get it direct from Paris, and not from agents, as it might be months old.

Mr. PEMBERTON: I get it in hermetically sealed tubes.

Mr. DEVINE: Yes, but you want to have it fresh. Some years ago, he tried all the different tuberculins on the market, and he found that M'Fadyean's tests were as good as any. He bought his tuberculin in five dose tubes, as it was better than getting the larger tubes, using only a portion at a time, and thus allowing the remainder to become stale. He was a great believer in the subcutaneous method of testing, and he had rarely got a doubtful reactor. Testing with tuberculin took up a lot of time, and carelessness often explained many of the uncertain results that were spoken to. He recommended them always to give a full dose rather than an under dose. They were more likely to go wrong with an under dose than with an overdose. He tested in ordinary cases at 3, 9, 12, 15 and 18 hours. As regards County Councils and auctions, he thought veterinary surgeons themselves had been very lax in not taking the opportunities that offered themselves under this Order, and if the local authorities did not do their duty when their attention was called to a case, he advised them to complain to the Board of Agriculture.

On the motion of Mr. Grasby, seconded by the Hon Sec., Mr. DeVine was thanked for his paper and his remarks.

Before separating the members partook of tea together.

H. J. DAWES, F.R.C.V.S., Hon. Sec.

SCOTTISH METROPOLITAN VETERINARY MEDICAL SOCIETY.

A meeting was held at Lanark on the 14th June. The members present were:—The President, Mr. Peter Wilson, Lanark; Prof. O. C. Bradley, Edinburgh; Messrs. J. Storie, East Linton; A. Baird, J. Riddoch, Prof. Gofton, and James Henderson, Hon. Sec., Edinburgh.

Visitors: Messrs. A. M. Trotter, Prof. J. R. McCall, Glasgow; H. Begg, Hamilton; R. N. Lewis, Dumfries; McDonald, of *The North British Agriculturist*; and Stirkie.

Apologies for absence were received from Professor Dewar, Messrs. Rutherford, H. Thompson, J. Aitken, T. P. Young, Bannatyne, D. M. Reid, J. Borthwick, D. Hamilton, W. Anderson, J. Player, Reid, J. F. McIntyre, J. Peddie, T. M. Inglis, McFarlane, and Peggie.

Those members and visitors who arrived at Lanark early enough were entertained by the President to a most enjoyable excursion to the Falls of Clyde, and afterwards to lunch at the Station Hotel.

The meeting began shortly after 3 p.m.

Mr. R. RUTHERFORD, proposed by Prof. Bradley, and seconded by Mr. P. Wilson, was unanimously elected Hon. Member of the Society.

A letter of resignation was received from Mr. J. Basil Buxton, and on the motion of the Hon. Sec., seconded by Mr. J. Storie, his resignation was accepted.

At our last meeting on 1st February, Mr. Cameron, of Berwick-on-Tweed, made a motion regarding the Milk and Dairies Bill, which was then under discussion, calling upon the R.C.V.S. to take active steps for its improvement, which motion was carried.

The following reply has been received from Mr. Fred Bullock, Secretary to the R.C.V.S.:

"April 14.

"Dear Sir,—I submitted your letter of the 8th inst. to the Parliamentary Committee at its meeting on Thursday last, when the Milk and Dairies Bill was under consideration. I have to inform you that a resolution was passed with regard to Section 2 of the Bill, as follows:

(a) *Milk and Dairies Bill.* "That in the opinion of this Committee the following amendments are required in this Bill: Section 2 (1) To substitute the words "to take with him" in place of the words "if accompanied by" in lines 6 and 7, the last clause thus reading: "and to take with him a veterinary inspector or some other properly qualified veterinary surgeon to inspect the cattle therein."

Section 2 (2) in line 21 to substitute for the words "and the cattle therein if accompanied for the purpose of the inspection of the cattle by a veterinary inspector or some other properly qualified veterinary surgeon," the words "and shall require a veterinary inspector or some other properly qualified veterinary surgeon to accompany him and to examine the cattle therein."

(c) That a Sub-committee consisting of Dr. Bradley, Mr. Garnett, Sir John McFadyen, Prof. Mettam, Mr. Mulvey, and the Solicitor be appointed to take such action as they may consider necessary for the purpose of securing the insertion of these amendments in the Milk and Dairies Bill and the Milk and Dairies (Scotland) Bill.—Yours faithfully,

(Signed) FRED BULLOCK.

New Members. Mr. JAS. PARK HAMILTON, M.R.C.V.S., Dundee; and Mr. R. R. ARTHUR, M.R.C.V.S., Auchtermuchty, having been nominated at last meeting were duly elected members of this Society, on the motion of Prof. Gofton, seconded by Mr. J. Storie.

MAN AND MICROBE: FRIEND AND FOE.

By Mr. J. STORIE, M.R.C.V.S., East Linton.

When Darwin wrote of the struggle for life that was continually going on throughout all nature, and which has had such a far-reaching influence on the evolution of all living things, he had in his mind's eye more particularly beings of the same species struggling and fighting for the necessities of life. Although he was not aware of the part bacteria took in this struggle by their production of disease, he was aware that the larger parasites did. He wrote, "The dependency of one organic being on another as of a parasite on its prey lies generally between beings far remote in the scale of nature." How significant and prophetic these words

were can only be appreciated now by our knowledge of microbic disease. When we think of the innumerable forms of life, animal and vegetable, we cannot comprehend any greater contrast, any two forms, further remote than man and microbe. Between these two perhaps the greatest struggle of all is taking place. Man, lord of creation, with dominions over the beasts of the field, the fowls of the air, and the fishes of the sea, and microbe the simplest and most insignificant to all appearance of living things. Can you picture in your mind's eye a tiny speck of jelly, so minute that magnified 500 or even 1000 times, its structure is so simple that unless stained it cannot be distinguished, and let the mind wander still further into the unknown and try to imagine a something that the most powerful microscope cannot picture and the finest porcelain filter cannot catch. Simply by their works ye shall know them. Nevertheless these little objects hold an unique distinction, in so far that there are certain species which are not yet by any means under man's control. They are even threatening his supremacy, and taxing all his ingenuity to keep them in check. We, as a profession, must take a foremost part in this great struggle against disease, and do our utmost to ensure man's victory over this pertinacious enemy.

There are many forms which, if properly handled, are of great economic value, but they hold a much more important place in the world's history. We depend on certain species for our very existence. No microbe, no man. Without the microbe, there would be no grass or vegetation, without the grass no flesh, and without flesh or its equivalent no man. In the past microbes have been looked upon by the ordinary observer as obnoxious little wretches, working mischief or dealing out death when ever they appeared. Now they are recognised as a power in the land. Friends far outnumber, foes. They abound almost everywhere in earth, in air and water. In the animal body there are scores of species. In dairying, in the curing of tobacco, in the tanning of leather, in brewing and distilling, in the purification of sewage, and in innumerable other processes which are daily increasing in importance and number they are invaluable, but by far their most important work is in the soil, where they act as scavengers, breaking down dead animal and plant matter. They also play an active part in nitrification. Without them the cycle of life could not be maintained. Their numbers in the soil can hardly be estimated. Cultivated soil teems with myriads of these minute forms of life—some for good, some for evil. They are most numerous at a depth of from 8 to 20 inches, and in a single inch of this soil (about 15 grs.), as many as 500,000 have been found.

In connection with farming, not many years ago tillage was looked upon as merely a mechanical operation, but a great advance was made when the biological aspect was opened up. There is perhaps no industry in which the study of bacteria is of greater importance to mankind than that of dairying. Cow's milk, in the first place, takes such an unique position as a food, especially for young children, that the presence in it of harmful forms of bacteria may have a serious effect. On the other hand, friendly forms have a most beneficial effect on the manufacture of butter and cheese. Since the discovery of bacterial starters the latter processes have been improved and simplified to an extraordinary extent. It is well known that milk which is, as I have already said, so valuable as a food for mankind, is at the same time a most suitable diet for bacteria, wherein they thrive and multiply. On this account, in certain cases it sometimes acts as a medium for the conveyance of most deadly poisons into the systems of young children. The fact that the necessity for a supply of pure milk is of vital importance has taken a long time to stir Parliament to take action in this matter. At last, how-

ever, what with the Tuberculosis Order and the Milk and Dairies Bill, matters appear to be in a fair way of being realised. From an economic point of view a most important victory has been gained.

FOOD PRESERVATION.

Perhaps no triumph of modern times over the microbes is of such great economic importance to this country as that over the putrefactive bacteria in the preservation of the nation's food. The refrigerator, assisted by our ships and the railway, have brought the sheep and cattle farms, the gardens and dairies of the whole world to our very doors. But for this victory our working people could not be fed. Without doubt the breeding and rearing of bacteria will become a science. Their good points and their bad ones will have to be studied, the useful varieties preserved and the others destroyed. New varieties will be produced, just as in the case of other plants.

PATHOGENIC OR DISEASE-PRODUCING BACTERIA.

Bacteria are divided into two classes, roughly speaking, saprophytes and parasites. The saprophytes live on dead organic matter. Parasites live and thrive on the living bodies of higher forms. Strictly speaking, the pathogenic or disease-producing type, belong to the parasites, although under certain circumstances the saprophytes may cause disease by their action on some parts of the tissues which may have become dead, by the production of their ptomaines, and no doubt there are others which may become parasitic on occasion. In comparison with the endless number and wide distribution of saprophytic bacteria—there are something like 2000 known species—there are in reality only few pathogenic species, perhaps 30 or more, known. A very few of these are able to perpetuate themselves outside the animal body, the better known are those of tetanus and anthrax. The great majority are dependent for their maintenance on other living bodies. They vary in an extraordinary degree as to how they affect animals, being pathogenic to one species and harmless, or almost so, to another.

Individuals of the same species of animal also show great divergence. Following infection by the microbe, one may be affected seriously, another slightly, and another not at all. In studying effects, both the micro-organism and the animal attacked must be taken into consideration. Much depends on the path by which the infecting microbes enter the body whether they produce disease or not. Certain species may come in contact with a breach in the skin and produce no bad effect, but the same if swallowed may give rise to fatal infection. Conversely, forms that are virulent when entering by a wound may cause no ill effect when swallowed.

The animal body is well protected against invasion. The body itself is covered with the skin which no microbe can pierce unaided. The mouth, nasal cavities, respiratory and digestive tracts are protected by a covering of mucous membrane, and the healthy stomach produces a powerful antiseptic in the form of hydrochloric acid, which should account for many species that may be swallowed.

The mere presence of bacteria in the body is not in itself harmful. Their action depends on the production of a chemical product which is known as a toxin. The virulence of any particular microbe is according to the quantity and quality of the toxin it produces. These toxins are only produced when the bacteria are multiplying, so that they may be present in fairly large numbers in some parts of the body without causing any disturbance. However, if some change takes place—a change to environment more suited to their habits, then they rapidly increase and their poisons become diffused throughout the system and produce disease.

What are the means of defence by which pathogenic

germs, even after their entrance into the tissues and fluids of the body are disposed of, or at least prevented from carrying out their depredations? The opportunities for such an invasion are so numerous, and the contact of animals with disease germs so constant, that but for some subtle power all would succumb. The power which enables the body to accomplish this is spoken of as resistance, and when specially marked, immunity. This may be possessed by an animal naturally—"natural immunity," or it may be acquired by an animal either by passing through an attack of the disease or by artificial means—by inoculation; this would be acquired immunity.

Susceptibility and immunity are problems essentially chemical, involving reactions between the tissues of the host and the toxins produced by the bacteria. If we are to understand disease so as to effect a cure, we must study these complex chemical reactions. In an outbreak of contagious disease among farm animals you must all have observed how the effects differ in the various individuals. One dies, another never displays a single symptom, and a third has a more or less severe attack. How do you account for these differences? Doubtless you will say it may depend on the number and strength of the infecting organisms. That may be true, but in considering the animals, you would say in the first place that the bodily health of each was different at the time of attack; possibly in the case of the one that succumbed, and the other that was severely attacked the powers of resistance would be less. Now, we must not confuse mere appearances of bodily health and strength with immunity to disease. What is this immunity then? In the first place the body is defended by the leucocytes or white corpuscles of the blood, and in the second place by certain bactericidal substances in the blood serum, which kill or render the invaders harmless. The leucocytes in the role of the defenders of the body are known as phagocytes or eating cells. It is not quite agreed whether they act as soldiers or scavengers, or perhaps both.

METCHNIKOFF'S THEORY.

When bacteria, or any foreign substance, gains entrance into the body, a definite reaction on the part of the phagocytes takes place at and around the place of entrance. Although at first a diminution in their numbers takes place, in a short time they are attracted in large numbers to the spot. They possess the remarkable power of penetrating the walls of the blood vessels. When we remember that these walls are entire, it is astonishing how they manage this without leaving any leakage or perforation. On the entrance of bacteria to a wound, for instance, the leucocytes congregate in large numbers in proximity to the breach and attack the invaders in quite a military style, and if in sufficient numbers, they doubtless prove the victors. Metchnikoff's theory is that the phagocytes both eat and digest the microbes.

EHRICH has a different theory. He believes that two substances must be present in the blood before immunity can be established. One to make the microbe vulnerable and the other to kill it. The microbe holds on to the first with one hand, and to the deadly bactericide with the other, and thus joins them together.

ALMROTH WRIGHT has still another theory. He believes that normal blood contains substances which he calls opsonins or cookers, that render the bacteria digestible before the phagocytes can absorb them.

There seems no reason to doubt, however, that the phagocytes play the most important part in the defence of the body against the attack of bacteria. Consequently, if any means could be discovered by which their numbers could be sufficiently increased, a great step in advance would have been made. In connection with this, chemical substances, known as auxetics, have

been found to increase cell proliferation. In this, as in the case of bacteria, we have to contend with foes as well as friends. Certain of them when applied to the multiplication of the leucocytes, if properly handled, may solve the problem of the treatment of microbic disease by their power of increasing the phagocytes sufficiently to destroy any number of bacteria which may gain entrance to the body. At the same time it has not been overlooked that the possible action of other auxetics on another class of cells may, by their abnormal increase, produce cancer. I am sure we hope and pray that this riddle may be solved soon, and whether these auxetics may be produced from gaswork's pitch or tar the discovery will not have been made a day too soon. If the cause of cancer was once known no doubt a means of cure or prevention would soon follow.

Attenuation of the Virus.—Bacteria can be cultivated and caused to vary widely in virulence, so that in many instances they can no longer do harm to animals which would otherwise succumb to their influence. Pasteur found that exposure to air, certain conditions of nutriment, varying temperatures, etc., had their effect. Anthrax bacilli, grown at a high temperature for 24 days lost their virulence so that they could no longer kill a sheep. He also discovered that the virulence of a parasite for one species of animal may be diminished by its growth in another. It was also known that the blood serum of a rabbit could kill unaided the anthrax bacillus. In this way he discovered that vaccines could be obtained which would induce a mild attack of disease such as would protect the individual from a second attack, just as vaccination with the lymph of cow-pox protects an individual against an attack of small-pox. In another way the virulence can be reduced by growing cultures in weak antiseptics such as carbolic acid.

Inoculation.—*Variola*. This prepared the way for the practice of inoculation which no one can doubt has a great future before it. The real struggle between man and microbe was inaugurated by the discovery in the first place that a person who had suffered from small-pox did not contract the disease a second time, and in the second place that the disease could be produced in a milder form by arm to arm vaccination, and in the third place, it was found that a person who had had cow-pox was immune to small-pox. For long it had been known that arm to arm vaccination produced the disease in an attenuated form, but this method had many drawbacks, and a fair percentage of deaths followed it. It was found later that the organism which produced small-pox was so much modified in its behaviour and virulence by its passage through the body of the cow, which is more resistant to the disease than man, that the practice of using calf lymph was instituted, and is that which is carried on at the present day.

The following diseases have been experimented with on the same lines, but with varying success.

Tuberculosis.—The tubercle bacillus was discovered by Koch in 1882. It attacks man, monkeys, cattle, horses, dogs, cats, pigs, and birds, reptiles and fishes. It is responsible for the death of one-eighth of mankind. It is undoubtedly the disease of animals that falls heaviest on agriculture, causing more ravages than all the other contagious diseases put together, at least such is the case in this country. Unlike other contagious diseases, which affect us more or less at intervals, tuberculosis pursues its course of destruction slowly but surely, in many cases the patient throwing out the deadly bacilli at the rate of thousands per day, unknown and unheeded by all concerned. In others it may lie dormant for months and for years in the body, holding its citadel against its enemies the phagocytes in some corner of the lung perhaps, ready whenever opportunity occurred to advance to attack any vulnerable point.

Drying seems to increase its resistive powers, it can deprive itself of all or most of its water and assume an inert form, and can survive without any nourishment whatever, and whenever it finds a suitable *habitat* can spring into active life at once and germinate like a seed. In the case of human beings the sputum is the greatest danger. A tuberculous patient spits on the floor, the sputum which may contain thousands of the microbes dries and mixed with the dust, especially in insanitary dwellings, rises and mixes with the air is drawn into the lungs where it may develop and produce the disease. This danger is equally present in byres where affected cows may be coughing and sneezing out infective discharges day after day. In badly ventilated and dirty buildings, you can imagine how the bacilli find a lodgment in the crevices of the walls and roofs where they may remain for an indefinite period in the dust and cobwebs, and, on being disturbed by flies or a gust of wind, drop into the air, fall on the food, into the milk pail, or may be inhaled by the other occupants of the byre. Outside the body the bacillus has great powers of resistance. It can live for a long time especially in dirt, dust, and darkness. Dried sputum has been found to contain live bacilli after two months. They resist putrefaction for several weeks and have been found alive in parts of a tuberculous lung that had been buried for the same time, they can withstand the action of the gastric juice for several hours.

The discovery of tuberculin by Koch has been of inestimable value in controlling the spread of the disease, as animals affected, however slightly, can be isolated, and if this were carried out faithfully the sources of infection would be greatly curtailed. Koch had great expectations of its curative effect, but we all know how disappointing the results proved.

Koch prepared his tuberculin by the following method: The bacillus is grown on sterile veal broth, to which has been added 1 per cent. of peptone, and 4 per cent. of glycerine. After six or eight weeks the culture is evaporated to one-tenth of its bulk over boiling water and filtered through porcelain. The filtrate is now tuberculin.

One of the greatest therapeutic triumphs of the 19th century was dependent on the discovery by Kitasato, a Japanese bacteriologist, that a person suffering from diphtheria could be cured by the injection of some of the blood serum of another animal that had recovered from the disease. If the toxins of the microbe of diphtheria be injected into the tissues of a horse, for instance, an antitoxin is produced. The horse is subjected to graduated doses, beginning with a few drops, (remember this is of the filtered toxin—no bacteria are present) and in the long run the horse can stand very large doses without any harm resulting. When in this condition the animal is bled in the ordinary way from the jugular, care being taken not to remove too much at a time and so weaken the animal. This can be repeated several times. The blood is allowed to coagulate, and the clear fluid on the top is the anti-diphtheritic serum which has the power of neutralising the toxins produced by the microbe of diphtheria in the human body. Under the treatment with this antitoxin the death-rate has fallen from 30 per cent. in 1892 to 9.6 per cent. last year.

CONTAGIOUS ABORTION IN CATTLE.

Next to tuberculosis, this disease causes more loss and disappointment to stockowners than any other. Medicinal treatment has been tried in every shape and form with but little success. Powerful antiseptics have been used, both externally and internally, but with little effect. Where rigid precautions have been taken regarding the disinfection of the discharges from the female, and disinfection of the generative organs of both male and female, by far the greatest success has been

obtained. Abortin, which is somewhat like tuberculin and mallein, has not as yet been a success, either as a diagnostic or preventive. Anti-abortion is another preparation which has been tried. It consists of virulent cultures of the bacilli and can only be used in non-pregnant cows. It has not been found a success either.

RABIES.

No discovery in connection with inoculation was hailed with greater thankfulness than that of Pasteur for the prevention of hydrophobia. Fortunately in this terrible disease the period of incubation varies from 40 to 60 days, so that there is usually ample time for its application.

The treatment consists in active immunity being produced with virus attenuated by drying, and administered during the long incubation period in doses of progressively increasing virulence. The virulence of the virus is regulated by the extent of the period of drying.

GLANDERS.

Thanks to the use of mallein, glanders is at least in a fair way of being controlled. Especially in London, where it was at one time so prevalent, the disease is being stamped out.

Mallein, like tuberculin, produces a rise of temperature in from 8 to 12 hours after injection, but it gives rise to a much more marked swelling at the seat of injection than does tuberculin. Its preparation is carried out much on the same lines as tuberculin.

TETANUS.

Although anti-tetanic serum has been in use for many years there is still great differences of opinion as to its efficiency as a curative. My experience of it personally was greatly in its favour to begin with, the first 8 or 10 cases which I treated with it recovered; latterly, however, I have not by any means had the same success. There seems no doubt, however, about its protective qualifications. In some districts it is used in all cases of serious wounds, and most successfully. Anti-tetanic is prepared in a similar manner to tuberculin.

Physical agents injurious to bacteria which can be utilised are dryness, light, and heat. Complete drying eventually destroys most of the pathogenic forms, although great differences of resistance are shown, some being killed in a few hours, while others, such as the T.B., can survive for a long time in a very dry condition.

Light—direct sunlight, is a most powerful germicide, except for a few species which exist in a manner similar to green plants. It has been found that exposure to direct sunlight will destroy the T.B. in a few hours. Well might we exclaim "Let there be light." What a reformation could be made in our byres and stables by the introduction of a sufficient number of skylights and windows, and if arrangements were made at the time for more perfect ventilation so much the better.

Heat is another efficient agent for sterilisation where it can be properly applied.

DISINFECTION OF BUILDINGS.

The disinfectants that can be used most effectively are hot lime waste and coal tar preparations in solution for buildings, and sulphurous acid for manure, not the least important part being thoroughness of application. There are spraying pumps on the market for this purpose which force the liquids into the most unget-atable corners and crevices of byres and stables. Under ordinary circumstances all these buildings should be thoroughly done at least twice a year. In connection with the animal itself much can be done when the bacteria are localised and can be reached. In the treat-

ment of abortion great benefit can be attained by giving injections of any of the approved antiseptics into the vagina and uterus, and into the prepuce of the bull. Much can also be done in dealing with the discharges from animals suffering from infectious diseases to prevent the particular disease from spreading, by treating these discharges with strong preparations such as sulphurous acid.

DRUGS.

It is doubtful if drugs prescribed internally to the host in the ordinary way have any great bactericidal action on parasites in the system. In many cases the host might be poisoned before the parasites become affected. Ehrlich, however, was struck by the fact that certain bacteria could be stained with a particular dye, and this led him to believe that the tissue in fact was susceptible to the dye that stained it. He believed that although a drug—say arsenic—was given to a patient suffering from microbial disease in the ordinary form, it would have no effect; you might poison the patient to an alarming extent without affecting the parasite, because the poison does not enter their bodies. Ehrlich's idea was to contrive what he called an amboceptor or two catcher, something like a stain that would hold on to the microbe with one hand and to the deadly bactericide with the other hand. In this way he prepared the compound, Salvarsan, known as 606, that being the number on the list of substances he had experimented with. This is the compound of arsenic which kills the parasites of syphilis and which has been of so great value to mankind.

The CHAIRMAN said they were all very much indebted to Mr. Storie for producing such an interesting paper. They had still a few minutes before train time, and if any one would like to speak in connection with the paper by way of discussion, they would be glad to hear them.

Prof. GOFTON said it was not just altogether an easy matter to pick up the various points for discussion in this interesting paper, for Mr. Storie had to hurry in the reading of it. One point that struck him was Mr. Storie's suggestion that bacteria operated largely, if not entirely, through toxins. He might be mistaken in what Mr. Storie said and what he meant, but he questioned very much if that could be accepted in all cases, and he was inclined to think that Mr. Storie took rather an optimistic view of toxins in the treatment and prevention of disease. One would not venture for a moment to belittle what had been done in this direction already, but he thought they had a very much longer way to go yet before they could claim any really high degree of efficiency in treating and preventing disease by means of toxins. At the present time he thought there was an inclination to attribute too much value to toxin methods in the treatment of disease. Another point which had struck him was in regard to the administration of drugs in the treatment of bacterial diseases. He was glad to hear Mr. Storie's remarks in relation to syphilis, but it was very hard to know how far they might yet proceed along these lines.

Prof. McCALL thanked Mr. Storie for his very interesting address. He was particularly struck with the practical manner in which Mr. Storie dealt with the subjects of the ordinary text-books. He was rather struck by Prof. Gofton's remark to the effect that serum treatment of disease perhaps had been over-estimated. Perhaps that might be applicable to disease in so far as they were concerned in this country, but he thought if Professor Gofton would refer to the work that had been done in this line abroad, and more particularly in America, he would see that the serum treatment of diseases had attained a considerable degree of efficiency, and was a treatment that was recognised by those in high authority. Another point that he had appreciated

in this paper very much was Mr. Storie's practical explanation of bacteriological methods. He should have liked if Mr. Storie had dealt a little more with the Tuberculosis Bill, and the relation of the bacteria in that connection. It was not an easy matter for a veterinary surgeon to come to a decision upon the presence or absence of tubercle bacilli, and particularly in relation to milk supply. He quite appreciated the objects of the authorities, but he thought the veterinary profession would find they would have considerable difficulty in coming to a definite conclusion as to whether the bacteria they were dealing with were actually tubercle bacilli or other bacilli.

Prof. BRADLEY said he did not pretend to pose as an expert bacteriologist, but he had some connection with the subject, practically and theoretically, and he should think there would be a considerable number of cases in which it would take not exactly a veterinary surgeon with ordinary knowledge of bacteriology, but take a bacteriologist, and one of great experience, to be able to say definitely whether they were dealing with tubercle bacilli or some other class of bacilli. That aspect of the Tuberculosis Order should not be lost sight of.

Prof. GORON said apparently he had not made himself clear in his remarks. He had no desire, and no intention, to belittle what had been done in the way of treatment with serum and toxins. What he meant to say was that the result of the value of that work was a tendency at the present time to presume upon it, and to carry it a little too far.

It was unanimously agreed to adjourn the discussion until next meeting.

JAMES HENDERSON, Hon. Sec.

Boarding out of Horses.

The "boarding-out" system, by which the War Office is endeavouring to maintain a reserve of trained troop horses is working successfully, the arrangement, so far, appearing to give satisfaction to both the Army Council and the "allottees." The system, however, does not wholly appeal to regimental officers who are naturally jealous of the care of the animals supplied them by the Remount Department. Their dislike of the system is perhaps responsible for the suggestion that those "boarded-out" horses, which were called in for manœuvres, imported mange from which the horses of so many units are now suffering. No evidence is yet forthcoming to substantiate that view. But assuming it to be correct, there must have been something radically wrong with regimental veterinary arrangements for horses in such condition to be accepted back on the strength. Several hundred horses have been dealt with under the scheme. As a rule, the horses are Irish-bred, eight years old, fully trained, and every care is taken to suit persons applying for them; they are delivered at Army expense, and a month's trial is allowed. The only cost to the "allottee" beyond keeping, is that of insuring the horse for £40, which costs roughly £2 per annum. The horses may be hunted, or used for any purpose save heavy draught, racing, or jobbing, but must not be put out to grass. They are liable to be called in for a month's training or manœuvres at Government expense, and on mobilisation must be given up immediately. Application for horses should be made to the officer commanding the nearest cavalry regiment, or to the Director Remounts at the War Office.—*The Daily Mail*, Hull.

BOLTON.—At 26 Woodland's Road, Shotley Bridge, Co. Durham, on the 6th inst., to Mr. and Mrs. W. T. Bolton, a son.

McGOWAN—ENGLAND.—A marriage has been arranged, and will take place at Bombay on the 25th October, between Major John A. B. McGowan, A.V.C., Ambala, son of John McGowan, Esq., Fair View, Millom, Cumberland, and Hester Geraldine, second daughter of Charles England, Esq., of Welton Manor, Brough, East Yorks.

MR. RICHARD ATHERTON NORMAN POWYS, Secretary of the Royal Veterinary College, Camden Town, N.W., left property valued at £1,010.—*Star*.

OBITUARY

THOMAS OLVER, M.R.C.V.S., Truro, Cornwall.

Graduated, Lond: April, 1867.

The death of Mr. Thomas Olver, which took place at Truro, on Saturday, 6th inst., has removed a very well-known figure. Deceased, who was 72 years of age, had been in indifferent health for the last two years, when he underwent a serious operation from which he never really recovered.

Mr. Olver was born at St. Mabyn, near Wadebridge, the son of Mr. Thomas Olver, a well-known farmer at Tresco, St. Mabyn. After qualifying in London he commenced practice at Truro 40 years ago as a veterinary surgeon, and in those early days was probably the only veterinary surgeon in the West of Cornwall. He held an appointment under the Privy Council, being one of its oldest officers, and afterwards served as an inspector under the Board of Agriculture. He was veterinary surgeon to the Royal Cornwall Agricultural Association for fifty years, and an inspector for Truro Division of the County Council. During the existence of the old Truro Horse Show, he for many years acted as hon. secretary. Mr. Olver also took an interest in the Fourburrow Hunt. He was never married, but leaves two brothers and a sister.—*West Briton*.

WILLIAM HOLLIDAY, M.R.C.V.S., Lazonby, Cumberland.
Lond: July, 1907.

At St. Pancras Station on Thursday, 4th inst., Mr. Walter Schroder held an inquest on the body of William Holliday, 30, a veterinary surgeon, and lately residing at Worship Street, London.

Mr. Robert Holliday, veterinary surgeon, Lazonby, identified the body as that of his son, who, he said, always enjoyed good health. For the last two months he had been employed at the Veterinary Infirmary, Worship Street.

Other evidence showed that on Monday evening, while the deceased was sitting in the waiting room of the departure platform at St. Pancras Station, he suddenly fell unconscious to the floor, and expired before medical aid could be obtained.

Dr. O'Donnell, who made an autopsy of the body, attributed death to syncope, owing to an acute attack of congestion of the lungs, while deceased was suffering from heart disease.

A verdict of "death from natural causes" was returned. Subsequently the body was removed to St. Pancras Station and entrained for Lazonby.

The funeral took place at Lazonby on Friday afternoon, and the huge gathering of mourners and friends spoke volumes for the place the deceased had made for himself in the affection of his neighbours, and for the respect in which his family is held in the locality. The

service was impressively conducted by the Rev. Canon Wilson. The deceased was a member of the Penrith Unanimity Lodge of Freemasons, and there was a large gathering of the brethren, those present including Messrs. J. W. Hewitt, W.M., T. H. Thompson, P.M., W. Scott, V.S., J. Barron, E. Story, L. Lamony, and G. Smiley, Penrith; Dr. Law, Kirkoswald; I. Longrigg, junr., and H. Smith, Lazonby; and W. Johnston, Langwathby. At the close of the service the brethren filed past the open grave and dropped into it the sprays of acacia.—*Cumberland Herald*.

CORRESPONDENCE.**THE STATE CONTROL OF TUBERCULIN.**

Sir,

I am one of many who look forward to, and carefully read your well considered and sage editorial remarks each week in *The Veterinary Record*, but those of us who are anxious that tuberculin should be placed under control must have been somewhat disappointed at reading your remarks on this subject in the issue of August 30th.

I need not enter into the question of whether this control is desirable or not, because this you fully admit, remarking that it would be "obviously desirable," "a good thing," and "would enable us to work under ideal conditions," but you proceed to enumerate what you feel are great difficulties.

1. That "no British Government would be at all likely to adopt it." May I say that the President of the Local Government Board, who would have to deal with this matter, has made first-hand enquiries and expressed himself, privately, entirely in its favour.

2. That it "would interfere with vested interests." We may ask what vested interest has not been interfered with successfully during the last few years? I need mention only two—beer and land. Compared with these, the vested interests, if any, in tuberculin are quite insignificant. If I thought it would do harm to the manufacturers of tuberculin I would not support it, but surely it is to their advantage to ensure that it shall only be employed by a properly qualified man who knows how to use it to the best advantage, and not to abuse it.

3. That "legislation could not be properly enforced." The distributing institutions are so few, and many of them even now are co-operating splendidly by refusing to sell tuberculin to any but veterinary surgeons, that it should be a comparatively easy matter to enforce. Besides, a herd of cows, or even a single cow, cannot be tested without a number of people knowing. We should also have the support of the majority of agriculturists, for as I indicated in a previous communication, they have expressed themselves entirely in favour of reform in this direction; in fact they are demanding it more strongly even than we ourselves.—*Vide The Farmer and Stockbreeder*.

4. That it "would make it a secret practice." It is almost impossible to conduct the tuberculin test secretly, but those owners who are now employing unqualified persons to defeat the operations of the Tuberculosis Order are not doing it publicly, otherwise they would not be able to sell their reactors in the market afterwards. There would be little difference on this score.

It is well that a subject of this sort should be thoroughly discussed from both sides, and it is with this idea that I venture to make these remarks.

Are the difficulties as great as suggested? Shall we veterinary surgeons wait for the agriculturist to again come to our help (e.g. the Milk Bill) and show us what should and must be done, not only to guard our interests, but what is more important, to protect the honest cattle owner and ensure a standard reliable tuberculin in the hands of those qualified to use it.—Yours faithfully,

G. P. MALE.

SEPTEMBER 20, 1913.

VOL. XXVI.

THE SCHOOLS.

During the week after next, all our schools will re-open their doors. The dates of the opening meetings have already been advertised, and only vary very slightly—from September 29th to October 1st. The meeting at Camden Town is this year of special interest, for Sir John M'Fadyean, who will give the inaugural address, is just completing twenty-one years of service there. It was in 1892 that Prof. M'Fadyean made his first appearance at Camden Town and delivered the inaugural address as the newly-appointed Dean and Professor of Pathology and Bacteriology. Coming from Scotland with a great reputation, he was understood at that time to be the future Principal of the School, and the next occasion on which he delivered the inaugural address—in 1894—marked his actual accession to the Principalship. We all know how the College has developed in his hands since then, and there should be a good attendance of old pupils to see him attain his majority upon its staff.

AN INFECTING AGENT IN TUBERCULOSIS.

A possible agent in the spread of bovine tuberculosis was mentioned at the Midland Counties discussion, which we printed last week.

Water from collieries has not usually been regarded as a source of tuberculosis; but more than one speaker at the Midland meeting cast suspicion upon it; and the name of Prof. M'Call was mentioned in support of the idea. On the other hand, Mr. DeVine—an acknowledged authority—expressed doubt, not seeing how such water could contain tubercle bacilli.

It is not easy to understand how colliery water can be directly infective, unless at some portion of its course it is liable to infection from tuberculous colliers. But there is some clinical evidence indicating infectivity; and we should like to hear if more can be adduced. The point is of practical importance, apart from its scientific interest.

Indirectly it has some bearing upon the vexed question of the channel by which cattle usually become infected. It may prove to be an argument of some value in the old controversy of ingestion *versus* inhalation. Water has been justly credited with conveying infection in various diseases, and tuberculosis may be one of them.

FRACTURE OF THE CUNEIFORM MAGNUM.

I think the following case which recently came under my notice, and of which I send a short description, with two photographs taken shortly after the accident, may be of interest to your readers. I regret that the photographs are very indistinct as I was compelled to take them in a very bad light, and the movements of the horse would not permit of sufficient exposure, but hope you will be able to make some use of them.

Subject. A five-year-old bay Australian mare, about 15 hands, the property of H.M. the King of Siam.

History. The mare was being led back to her stable which is built on piles, and stands about four feet above the level of the ground. To enter the stable it was necessary for the mare to walk up the inclined boarding shown in the accompanying photograph. Whilst doing this she slipped and fell. Being unable to rise, temporary slings were erected and by this means she was raised to the standing position, when it was found she was unable to bear any weight on the off hind. The limb assumed an abnormal position, appearing longer than its fellow. The point of the toe rested on the ground, whilst there was excessive flexion of the hock and fetlock joints. When viewing the injured hock from either side, it had the appearance of a very pronounced curb.

On manipulation there was distinct crepitus and increased mobility evident in the hock joint; these

symptoms being particularly marked in movements of abduction and adduction of the metatarsus, but pain was not marked.

The following morning there was a moderate amount of hard swelling, chiefly confined to the inner and posterior aspects of the hock, and the mare was shot.

On post-mortem examination the cuneiform magnum was found to be completely fractured from anterior to posterior border in almost two equal parts.

H. G. TABUTEAU-HERRICK, M.R.C.V.S.

Royal Stables, Bangkok.

July 26th.

[The second photograph unfortunately would not "reproduce."].

ABSTRACTS FROM FOREIGN JOURNALS.

HERNIA OF THE POINT OF THE CÆCUM IN A MULE. —RADICAL CURE.

Auger records (*Journal de Méd. Vét. et de Zootechnie*) the case of a four-year-old mule which presented, towards the inferior third of the right flank and rather posteriorly situated, a soft depressible swelling the size of a child's head, which was easily returnable into the abdomen. Auger could easily make out the circumference of an almost circular hernia ring of about 10 to 12 centimetres (= 4 to 4½ inches) in diameter. The diagnosis of ventral hernia was therefore established with facility, and was also supported by the history. The animal had been pastured amongst cattle, and had received a violent blow in the right flank from the horn of one of them about three months before.

Having thrown the animal, Auger found that the hernia was easily reducible; but after returning it to the abdomen the sac appeared thicker than normal. He decided to attempt radical cure by suture.

Twenty minutes before the operation the mule received an injection of morphia and atropine. He was thrown upon the left side, and then anaesthetised with chloroform.

Having taken antiseptic and aseptic precautions, Auger made two curved incisions, each about eight to ten inches long, meeting at the ends and isolating a piece of skin from 2 to 2½ inches broad over the hernia. He then separated this piece of skin from the sac, and removed it. Next he dissected the sac from the skin as far as the opening of the hernial ring. The sac appeared to be free from adhesions, although its walls were rather thick.

Auger then secured the sac with forceps, and made an incision from 1½ to 1¾ inch long in it. To his great surprise this incision opened into a pouch containing alimentary material, extending upwards into the abdomen, having a volume equal to that of the sac, and adhering to the latter throughout its extent. Considering the shape of this intestinal pouch, there could be no doubt that it was the point of the cæcum which had lodged in the hernial sac and become adherent to it.

The intestine was now separated from the sac and solidly sutured. The adhesions which the cæcum had formed were then broken down, and the hernia was returned into the abdomen.

The rupture in the abdominal wall was then closed by sutures, and a clamp of Marlot's pattern. Although the abdominal wall around the hernial ring was very thin, the results were excellent. The temperature never rose above the normal. At the end of twelve days the sutures and clamp were removed. By that time the cicatrization of the muscles was perfect, but as some skin had undergone necrosis from the pressure of the clamp, a rather large cutaneous wound was left. This cicatrised in a month's time, and the cure was then complete.—*Annales de Méd. Vét.*

VARICOSE TUMOUR OF THE VAGINA IN A MARE.

Hartog records (*Tydschr. voor Veeartsenijkunde*) the case of an aged mare, some months pregnant, which frequently showed a hæmorrhagic discharge from the vulva. These repeated losses of blood had brought about a very pronounced anæmia.

Careful exploration of the vagina revealed the existence upon the roof of the vaginal wall, about six inches in front of the vulvar commissure, of a duplicature of mucous membrane which was hanging in the lumen of the vagina. At its base it had the dimensions of a two-franc piece.

A constant hæmorrhage was being produced from this place, and became accentuated at the moment of the vaginal exploration. It was possible to almost totally efface the tumour by compressing it with the finger, and when this was done the hæmorrhage ceased. These manipulations did not cause the least sign of pain. The blood presented the characters of venous blood. Hartog diagnosed a varix which had induced anæmia as a consequence of repeated losses of blood.

By means of a speculum, Hartog dilated the vagina sufficiently to enable him to apply a ligature to the base of the tumour. When this was accomplished the hæmorrhage immediately ceased, and the part compressed in the ligature came away at the end of seven days. The general condition of the mare improved rapidly, and the only after-treatment that Hartog adopted was the introduction of a capsule of bacillol into the vagina twice daily.—*Annales de Méd. Vét.*

W. R. C.

REPORT UPON THE INVESTIGATIONS OF THE PECTORAL FORM OF INFLUENZA OF THE HORSE (BRUSTSEUCHE) AT THE ROYAL INSTITUTE OF INFECTIOUS DISEASES.—GAFFKY (*Ztschr. Veterinärk.*, 24 (1912), Nos. 2, pp. 65—76, fig. 1; 3, pp. 113—122; abs. in *Rev. Gen. Méd. Vét.*, 20 (1912), No. 230, pp. 77—79).

This paper presents the results of bacteriological studies, investigations of the histogenesis of primary lesions, period of incubation, experimental inoculations of laboratory animals and horses, and the role of rats, mice, and insects in the transmission of the disease. In studies of 4,000 slides made from

523 fragments of various organs, the author failed to detect the presence of any causative organism. Sarcosporidia were frequently found in the diaphragm and intercostal muscles but were present in healthy as well as affected horses. Attempts to cultivate an organism aerobically and anaerobically from the lung tissue, blood from the lungs, pleuritic exudate, spleen pulp, etc., on various media containing blood serum resulted negatively. Two colts, six months of age, were slaughtered on the 60th and 62nd hour respectively, after having ingested faeces and having been inoculated with discharges from the affected animals (with which they were placed in contact) with a view to determining the tissues first attacked; in one a pneumonic focus with pleuritic infiltration was present, in the other a simple localised pulmonary oedema. The intestinal wall of both animals was equally inflamed in places throughout its length. These investigations indicate a priority for the intestinal lesions, but further investigations are considered necessary in order to settle the question.

The incubation period was found to be about 30 days. Laboratory animals inoculated with, and fed upon various infected products, proved to be refractive, and similar results were obtained from six horses to which various products from infected animals, including intestinal contents and fragments of pulmonary tissue, were fed. In an attempt to determine their possible role in the transmission of the infection, horses were fed upon the droppings and bodies of rats and mice which had been kept in cages into which dung from affected horses was introduced almost daily for nearly a month, but with negative results. Transmission experiments with various insects and arachnids resulted negatively.

ON THE ETIOLOGY OF THE PECTORAL FORM OF INFLUENZA ("MALADIE" TYPHOIDE) OF THE HORSE.—J. LESAGE (*Bul. Soc. Méd. Vét.*, 89, (1912), No. 20, pp. 498—513).

The author thinks that the influenza of the horse is a diplococcic septicæmia, and that the diplococcus pneumo-enteritis equi of Galtier and Violet may be the causative organism.

SALVARSAN AND ITS ADMINISTRATION IN THE PECTORAL FORM OF INFLUENZA IN THE RUSSIAN ARMY.—I. GORDSJALKOWSKY (Abst. in *Berlin Tier. Woch.*, 28 (1912), No. 39, pp. 720—721; *Amer. Vet. Rev.*, 42, (1912), No. 3, pp. 350—352.)

The satisfactory results following the administration of salvarsan subcutaneously in 23 preliminary cases, led to its use in the Russian Army in January, 1911. In order to determine its therapeutic effect when injected into the blood, experiments were carried on with 50 horses; in four cases the injections were made immediately after the detection of the disease, in 35 cases on the second day, and in three cases on the third and fourth days.

The temperature usually fell six or eight hours after administration, and after 48 hours was again

normal, the inflammation of the lungs and pleura disappearing at the same time. A second administration was necessary in six cases, as the temperature rose again, after a period of from two to four days, to 104 F. These horses were first treated with 2 gm. of salvarsan, and the second time with 1 gm., which proved to be sufficient to insure complete recovery.

Other horses in which the symptoms were less severe, were given doses varying from 1 to 1.5 gm. In these cases, after a slight recovery, a partial relapse occurred which necessitated a repetition of the injection, whereupon a rapid recovery followed. In the one fatal case among the horses treated with salvarsan the temperature increased and reached 108 after four hours.

It is stated that the dose administered to young horses of 1100 lb. should not exceed 2 gm. It is recommended that the administration be made at the outset of the disease, using a solution in the proportion of 1:500, which should be administered intravenously.

ON THE TREATMENT OF THE PECTORAL FORM OF INFLUENZA (BRUSTSEUCHE) OF THE HORSE WITH SALVARSAN.—NEVERMANN. (*Berlin. Tierarztl. Wchnschr.*, 28 (1912), No. 14, pp. 241-246).

Thirty-eight horses suffering from the pectoral form of influenza were treated with salvarsan, which was administered in 2 to 3 gm. doses, intravenously in 27 cases and intramuscularly in 11 cases.

Two of the 27 animals to which the salvarsan was administered intravenously died; in one, death was either due to paralysis of the heart as direct result of an intoxication, or to an embolus; in the other case, to necrotic pneumonia. Ten of the other 25 cases to which the salvarsan was administered intravenously had a normal temperature within 24 hours, and the temperature of the remaining 15 had fallen more or less. In one case a second administration of the drug was necessary. In all cases a thoracic dulness was present at the time of treatment and in six of the fourteen remaining cases a dulness appeared during the further course of the disease.

In the 11 animals to which salvarsan was administered intramuscularly the beneficial influence of the drug on the further course of the disease was not so constant, since a thoracic dulness developed in five of the six animals in which it had not appeared at the time of treatment. The body temperature of these animals was not influenced by the treatment. See also a previous note. (*E.S.R.* 27, p. 289).

ON SALVARSAN IN TREATMENT OF THE PECTORAL FORM OF INFLUENZA (BRUSTSEUCHE) OF THE HORSE.—KETTNER. (*Berlin. Tier. Woch.*, 28 (1912). No. 26, pp. 855, 856).

This is a brief general review of the subject, in which the author calls attention to the beneficial results obtained from the use of this drug.

FORAGE POISON IN HORSES, CATTLE, AND MULES, SO-CALLED CEREBRO-SPINAL MENINGITIS AND COMMONLY TERMED "STAGGERS."—R. GRAHAM. (*Kentucky Sta. Bul.* 176, pp., 369-383, pls. 4).

An outbreak of forage poisoning traceable in a majority of cases to unsound corn, fodder, or fermented ensilage is said to have occurred in Kentucky during the fall and winter months of 1911-12, the heaviest loss being recorded in Kenton, Marion, Henderson, Boyle, Fayette, Warren, Scott, Mason, Marshall, Boone, Pulaski, Shelby, McCracken, Graves, Montgomery, Jefferson, and Fleming counties. Horses were attacked more than cattle, and cattle are more susceptible than mules.

The author states that the course of the disease was so varying that it may be described as occurring in two and perhaps three types, the acute or rapidly fatal; the subacute, which generally ends in death; and the chronic or milder form from which the animal under proper care and treatment may recover. It was often observed in cattle that the first animal affected in the herd died much sooner than the animals subsequently attacked. Some animals made a complete recovery from a mild or chronic form of disease only to succumb in a few days or a few weeks' time on a recontraction of the disease, showing that one attack confers no resistance to a second.

The acute form is said to have been more prevalent than any other, especially in horses and mules, the animals so affected succumbing in from two to three days from the time the first clinical symptoms were manifested. Animals were frequently found dead in the morning that evidenced no symptoms of ill-health on the previous day. Horses were attacked at work in the field and died within a few hours. It is stated that the peracute types of the disease have been mistaken for acute poisoning, numerous sample of stomach contents from such animals having been received at the station for examination. The symptoms in a majority of the acute cases were of from 12 to 72 hours standing, while symptoms of subacute cases were of three to nine days duration. The symptoms of the chronic form are mild, such as loss of appetite, dullness, slight inco-ordination in walking followed by recovery in two or three days.

In response to a set of questions sent out to veterinarians in the State, reports were received of the deaths of 100 of 134 cows affected, 465 of 612 horses, and 99 of 115 mules. Bacteriological examinations of the brains of several horses and cows gave negative results.

Two veterinarians reported slight success in treating the disease by intravenous injections of a solution of Pot. permanganate. The best method of combating it lies in prevention; mouldy, improperly cured, fermented, or damaged feed should not be fed to animals. It is stated that at the Elmendorf farm, one of the largest stock farms in this country, where the damaged corn was floated and only sound corn fed, no cases appeared.

F. E. P.

EASTERN COUNTIES VETERINARY MEDICAL SOCIETY.

A meeting was held on Thursday, Sept. 11th, at the Royal Aquarium at Yarmouth. The members first lunched together, after which a short business agenda was discussed. In the absence of the President, a Vice-president, Mr. W. L. Little, Yarmouth, was elected to the chair, and the other members attending were Messrs. W. Shipley, Yarmouth; E. Margaron, Swaffham; P. Turner, Ixworth; E. A. Hudson, Barrow; T. E. Anger, Wymondham; H. E. Wilkinson, Martham; A. Holl, New Buckenham; W. Waters, Blofield; J. F. Thurston, Fressingfield; Sidney Smith, sen., Lowestoft; G. Macintyre, Loddon; T. Love, Paston; J. Buckingham, Harleston; M. Bray, Docking; and Sydney Smith, jun., Lowestoft, hon. sec.; with, as visitors, Messrs. C. Boreham, Colchester; R. P. Turner, Ixworth; and W. Shipley, jun., Yarmouth.

Apologies for absence were received from the President, Mr. F. B. O. Taylor; Messrs. E. H. Leach, T. G. Heatley, F. L. Gooch, J. E. Kitchen, F. Morton Wallis, J. Hammond, sen., H. P. Standley, H. V. Low, J. Robertson, J. J. Scott, T. E. Barcham, H. F. Downe, D. S. Jack, H. Buckingham, J. Barr, A. F. Castle, and A. C. Holl. Prof. Hobday wired from Horning that a motor breakdown prevented his attending.

The Hon. Sec. said that 19 members failed to reply. He also announced that at the next meeting he should tender his resignation so that anybody who wished to take up the duties would have time to consider it. His resignation was due to several reasons, and having been Secretary for three years he thought that he had done his little bit for the Society.

Resignations. The Hon. Sec. read a letter from Mr. F. B. O. Taylor from Stratford-on-Avon, stating that as he had now left Norfolk he desired to resign, which he was sorry to do, as he had always enjoyed attending the meetings.

A similar letter was received from Mr. R. B. Palmer who had left North Walsham for Warwick.

Mr. W. SHIPLEY moved that a letter be sent to each gentleman expressing regret at their removal and conveying the good wishes of the members for their prosperity in the districts to which they had gone. He alluded to the fact that Mr. Taylor acted as Hon. Sec. of the Society for some years.

Mr. SIDNEY SMITH seconded, and this was carried unanimously.

Next Meeting. On the proposal of Mr. W. Shipley, seconded by Mr. E. Margaron, it was resolved to hold the next meeting at Norwich.

TUBERCULOSIS.

The Hon. Sec. announced that Mr. Sidney Villar had consented to read his paper at the next meeting.

A FEW CASES OF INTEREST.

By Mr. WILFRID WATERS, M.R.C.V.S., Blofield.

Gentlemen,—When our Secretary asked me to read a paper at this meeting, I decided to bring before your notice a few cases which had proved of special interest to me, in the hope that they might also appeal to you, and so be the means of evoking a good discussion.

FRACTURES IN FOALS AND COLTS.

A few years ago there appeared in *The Veterinary Record* several articles on the desirability of setting fractures in cattle, and having been very successful in the treatment of bovine fractures myself, I made up my mind that I would try my luck with foals or colts whenever I had the chance. I have had two such cases which I will describe.

Case I. On March 24th, 1910, I was called to see a valuable Shire filly foal by "Redlynch Forest King," three days old, suffering from a fractured humerus in the near fore leg, probably as a sequel to being stamped upon by the mare. Not being able to affix splints and bandages so high up in the leg, I simply applied a pitch plaster from the top of the scapula to the radius. All the straw in the box was replaced by chaff and the foal left there to take its chance. In about three or four weeks the foal began to use the broken limb, and eventually made a very good recovery, in fact the broken leg is now the better of the two, because unfortunately as a result of having to support all the weight for five or six weeks, the off fore leg became very pigeon-toed, and is so to this day. The filly, however, is able to work alright, and is likely to make a valuable brood mare.

Case II. A yearling filly, suffering from a fractured radius of the near fore, the sequel to a kick. I tried to set this case by means of splints and adhesive plaster bandages, but when the swelling in leg began to subside two or three days after, the bandages got loosened and slipped off. I then decided to apply a pitch plaster, as in the previous case, and the filly made an uneventful recovery, and was sold six months later for 21 guineas at a public auction.

A PECULIAR SHIVERER.

In Oct., 1910, a client purchased a three-year-old cart colt at a Michaelmas sale, and on its arrival home, worked it on the farm without shoes till Christmas time. Then when the land got harder, he sent it to the blacksmith to be shod, and was much surprised to have it returned, as the farrier found he could not lift his front feet up. I was called in to see the colt, and found that he could trot quite freely, could back without his tail quivering and seemed to all intents quite sound, until one tried to lift his fore feet up. Then he would begin to tremble all over and bear his whole weight on the limb you had hold of, so making it an impossibility to get off the ground. I tried him with a rope over his shoulder to no effect, and even put him into slings so that we might shoe him, but all to no avail. Finally we had to cast him to shoe, and this was done periodically every few months until he was sold a short time ago.

One of the peculiar features about this case is that the farrier always shod his hind feet without any trouble right to the end. Finally, I might add, that three or four months after I first saw him he gradually developed into a typical shiverer, i.e. lifting his tail and hind legs when made to back, so there is no question in my mind that the symptoms I have described were due to "shivering."

DISLOCATION OF THE CARPO-METACARPAL JOINT.

I was asked to see last April a bay pony which had got entangled in an iron hurdle, and had injured itself. Upon examination I was surprised to find that the knee joint was dislocated, the leg being bent at such an acute angle that it was almost impossible for the pony to get the toe of that limb on to the ground; and, figuratively speaking, one could hang one's hat on the proximal end of the metacarpus. I tried in vain for half-an-hour to reduce the dislocation, and at last went home to get my hobbles and chloroform apparatus. The pony was cast very easily, leaving the affected leg unhobbled, and much to my surprise, on examining the limb directly afterwards, found that the dislocation had reduced itself. The pony was naturally stiff for a few days, but made an uneventful recovery. My reason for recording this case is its rarity.

A PECULIAR CASE OF REDWORM.

In April, 1909, I received an urgent message one evening about 9 o'clock to see a mare presenting the following history, symptoms, etc. The subject was an eight-year-old cart mare in the pink of condition. She had been in regular work until 1 p.m. that day, and was only left in the stable that afternoon because she was not wanted. Nothing was noticed amiss with her at tea time, but she was found very ill at 9 o'clock.

Symptoms.—Temp. 105 F., pulse weak and over 100, brick red condition of conjunctival mucous membrane, violent purgation, cold perspiration; no apparent pain, but in a general state of collapse.

Prognosis.—Decidedly unfavourable.

Diagnosis.—I first thought she had ruptured a blood vessel, but of course the colour of the mucous membrane negated that. I also thought of "redworm," but the age and condition of the mare seemed to contra-indicate that, so beyond telling the owner that she was dying, I made no diagnosis. She gradually got weaker, and died at 5 a.m. next morning.

Post-mortem.—The intestine from beginning to end was nearly black with enteritis, the inside lining of the gut was literally covered with sclerostomata tetracantha, and finally there were three ruptures in the large colon, through each of which one could pass one's finger. These ruptures were evidently made direct by the redworm passing through the bowel wall, for in each rupture the worms were in close proximity to the edges of the wound.

Remarks.—This case is, I think, of great interest when one considers the age and condition of the mare, and also that she had been working within a few hours of death, in spite of the intense enteritis.

RANKNESS IN SPAYED SOWS.

During the past year I have been greatly annoyed at receiving complaints from farmers to the effect that a large proportion of sow pigs in certain litters that I had spayed had not been cut clean. A man always knows when he has left an ovary in a sow, but in the litter about which I received the complaint I felt positive that such was not the case. About three months ago I spayed five litters for one client, which pigs varied in age from five to seven weeks. A few days later I was asked to see them, and found that practically every sow had vulva greatly inflamed and looked fit for service, which was especially noticeable in the younger sows of only six weeks of age.

I was unable to account for the trouble, but told my client I would pay him £1 if he cared to kill any sow pig in the five litters and find an ovary. This offer was declined. Fortunately for me a few days later this client purchased two litters of pigs, which had been spayed by another veterinary surgeon previous to purchase. Within a week all the sow pigs of these two litters became affected in the same way. Being asked to advise in the matter once more, I enquired carefully as to their method of feeding, and found that directly they were taken off the sows—the time also that they were spayed—their diet consisted largely of wheat, which had been so heated and damaged, as a result of last year's bad harvest, that it was valueless to sell, and so was used as pigs' food. Being suspicious of this article of diet, I went round to all my clients who had made complaints and found that in every case their pigs had been fed on damaged corn, principally wheat.

I should like to ask the members present if they have ever had any similar trouble, and also if they can explain, physiologically, the reason for damaged wheat affecting the vulva in this way. Personally, I think there seems a great similarity between this case and

that of laminitis in horses caused by eating too much wheat.

TORSION OF THE UTERUS IN A MARE.

On May 9th, 1913, at 6 p.m., I received an urgent message to attend a mare which was unable to foal. On my arrival I learned that the mare showed labour pains when on the plough at 9 o'clock that morning, and so was brought home. Much to owner's surprise, although her labour pains kept coming on every few minutes, they never seemed sharp enough to cause her to strain and so burst her water bladder. I found the mare's temperature and pulse to be about normal, and on introducing my hand within the vagina everything seemed natural, although there was no appearance of foaling, the os uteri being quite closed. The mare kept walking round and round the box, then dropping to the ground in pain, only to jump up again almost directly without showing any tendency to strain. I was inclined at first to regard it as a case of colic, but the bowels seemed quite active, and the mare dunged and staled regularly about every half hour. I prescribed a laxative drench, but refrained from sedatives, as I did not wish to retard the labour pains.

These symptoms went on unceasingly from 8 a.m. on May 9th to 6 p.m. on May 11th, and although at times the mare suffered fearful agony and was white with foam, she never showed any tendency to strain.

At 6 p.m. on May 11th I received another urgent message, and found that she was now straining violently and passing a few drops of liquor amnii. On passing my right hand within the vagina I found the os uteri to be partly opened, but to my surprise I was unable to effect an entrance to the uterus.

I now inserted my left hand and found that directly I passed through the os, if I turned my hand sharply to the right, I was able to enter the womb and find the foal tucked into the right flank of mare. Of course, I now saw that I had a case of torsion of the womb to deal with, so inserting my left arm again I tried to work the womb back into its correct position by moving my arm towards the left flank. After a time I was able to straighten the womb a little, and with my left hand managed to rope the fore legs and head of foal, and when these were pulled steadily towards the left side of the mare, we were able to deliver the foal and right the uterus at the same time.

The mare was naturally very weak and almost in a state of collapse, so we gave her half a pint of neat whiskey, rubbed her up, and rubbed her all over with embrocation. Next day she had a temperature of 104 F., but showed no symptoms of metritis. On the following day her temperature dropped almost to normal, and she passed out of my hands on the 14th.

Remarks.—I consider I was very fortunate in being able to foal this mare so easily—it only took about half an hour—as I quite expected I should have had to resort to chloroform, and perhaps roll her down hill. I should like to draw attention to the fact that, in spite of her being in labour 58 hours, she had no inflammation of the womb or uterine passages. This was undoubtedly due to the fact that she did not strain at all throughout her long period of labour.

HODGKIN'S DISEASE IN A DOG.

On August 13th last, I was requested to see an aged Scotch terrier, as the owner thought he was suffering from goitre. I was surprised to find about 15 tumours under his throat in the region of the larynx, which tumours varied in size from a filbert to a hen's egg, were quite painless, and but for pressing on the larynx seemed likely to cause no inconvenience. The temperature was normal, appetite good, but there was a slight cough, and on examining the mouth I found the tonsils were greatly inflamed.

Diagnosis. First I assured the owner it was not goitre, and then had to admit I could not give the complaint a name, but thought it was some bacterial infection which had reached the glands of the throat by means of the tonsils; consequently I prescribed liberal doses of Pot. iod. internally and liniments externally.

Four days after the first visit two more swellings appeared, one on the point of each shoulder. As these tumours did not appear to alter in size or consistence, on Aug. 26th I asked Mr. Wilkinson, of Martham, to see him with me. As a result of this consultation we were at first inclined to think it a case of melanosis, but the inflamed condition of tonsils negated that, so we left the diagnosis an open question and prescribed a course of arsenic as a change.

On Sept. 2nd, as dog had made no progress and other swellings had made their appearances, one beneath the tongue and one near the penis, the owner requested me to poison him. I was not allowed to make an exhumation post-mortem, but permitted to remove two or three tumours for examination. One of these I sent to London, and had a report from Mr. Sheather to the effect that the so-called tumour was an enlarged lymphatic gland, and that from the symptoms I had described he had no doubt it was a case of Hodgkin's disease.

On looking up this complaint in my pathology notes I find it is a disease in which many, or may be, the whole of the lymphatic glands of the body are greatly enlarged, the cause of condition being obscure. The enlargement appears to be due to the addition of lymphocyte cells to the gland substance, and contrary to what one might expect there is no increase in the number of leucocytes formed, and there is usually a more or less marked anaemia resulting in death.

DISCUSSION.

The CHAIRMAN said these notes were of much interest and the members were all obliged to Mr. Waters. Fractures especially interested him, because a good many people, himself included, when called to fractures in colts or other animals slaughtered too soon, instead of giving them a trial. He remembered a steer bought at market, and the owner on getting it home found it had a broken metacarpal bone. It was set in plaster of Paris and had done so remarkably well that he was encouraged to try other cases.

Shivering in the fore leg was very rare and cases of the sort appeared quite mysterious. The case of redworm was very singular, but Mr. Waters did not say if there had been any peritonitis. If there was peritonitis present that was the cause of death. If there was no peritonitis the rupture did not count to any extent so far as the death of the animal was concerned. With these ruptures, especially as they were not very large, the animal would not have died without peritonitis. The sclerostomum armatus weakened the bowel for more than the tetracanthus. The armatus was very destructive toward its hosts, perforating the bowel or weakening it so that it was very liable to rupture.

He did not castrate many sows, and this year was the first time he had had any complaint of sows coming into season after the operation. He did them properly but ceased to worry about it after he heard that the Suffolk gentlemen who were experts were having the same trouble.

The case of torsion struck him as being rather one of displacement possibly through one of the ligaments becoming ruptured or elongated and allowing the womb to come to the flank.

Mr. W. SHIPLEY said he wished to congratulate Mr. Waters on his interesting notes because he was prepared to admit some of his failures, which men did not often do. At the same time Mr. Watson had related cases that were neither stupid nor trivial. The steer to which the Chairman referred which fractured a leg he

believed would be one of the best seen at the Christmas sale. When the farmer showed it to him two or three months ago he did not recognise which leg was broken. It showed the possibility of setting fractures in certain cases with success. Shivering in the fore legs was very interesting, and he wondered whether it was a positive case of shivering, and if so it should have been kept under observation, as their knowledge of shivering at the time was limited. He had always presumed shivering was progressive from the posterior portion of the spinal cord anteriorly, but Mr. Waters' case commenced in the fore legs and eventually developed in the hind legs. Dr. McCall, of Glasgow, had made numerous experiments and taken sections of the spinal cord, with no very great results, and a condition of this kind might be helpful to him. It might be that while looking for the seat of shivering in the cord in the lumbar region they ought to look right away up to the motor sections of the brain. He once examined a stallion that had decisive stringhalt in one fore leg which was very peculiar, and though he felt certain, his opinion was not supported by other people. When led a little way he suddenly brought up his fore-leg, jammed it on the ground and went on again comfortably.

The question of redworm should receive more attention. Many cases of acute enteritis in five or six year old horses might be caused by redworm, though they did not always appreciate it. In many cases where death occurred from redworm there was supposed to be septic poisoning through absorption of matter due to ulceration or excoriation of the mucous membrane of the intestines.

He could not understand why feeding young sows on heated wheat should produce the condition described, but it was quite a reasonable suggestion. In Suffolk there had been a certain amount of reflection cast on veterinary surgeons who, it was thought, had not done the spaying properly. Some veterinary surgeons had suggested that there was some sort of septic vaginitis. They ought not to be content, and should go further to find out some other cause why heated wheat acted in this way. He suggested the Chairman should relate a case of torsion of the uterus in which he assisted him, and in which the result was satisfactory, because it showed a man working single-handed in a difficult case might succeed with a little help.

The CHAIRMAN said a man sent for him to see a mare which he said was foaling, but he thought it was colic. Next day the man sent again and said she had more pain. He did not examine her, as he did not suspect foaling. The following day he was told she was down and straining badly. He examined per vaginam, and found it very difficult to get his fingers into the womb. Mr. Shipley assisted him, and when they got their hands in the first thing they grasped was a foot. After a time, by rolling her they managed to get this foot into the opening and get a rope on to it. By holding on to this and rolling her from side to side they got the rope on to both legs and the jaw. Finally they managed to right the womb, the os became larger, until they got some portion of the foal out by traction, and it was delivered. The mare was under chloroform, and she was ill for some days, but she made a good recovery.

Mr. SHIPLEY said one of the most important things was that they cast the mare and chloroformed her. While manipulating the outside of her abdomen they were able to push the fetus and uterus more or less into proper position. The result was most successful, for he never anticipated the mare would live, but she did, and was afterwards served by a stallion and sold. It was a complete twist. He once went to a cow with a twist in the neck of the uterus, and by casting her delivered the calf. The following year he was called to the cow, but this time could not untwist the neck of the uterus. He could do nothing, and therefore cut the aorta, but

even when she was dead they were absolutely unable to move the uterus.

Mr. THURSTON said he saw in *The Record* some years ago a report of a lawsuit brought on the Continent by the owner of some pigs which became rank after spaying, against the castrator. Needless to say he lost his case. The pigs had been fed on sprouted corn. He had his attention called to some pigs on which he had operated during the season, and he found in every case they had been fed on sprouted grain. He was once called to a heifer with a fractured leg, which he put in plaster and it mended. This particular animal had, in all, four fractures. Only one leg was unfractured, while one leg was fractured twice.

Mr. HUDSON said he had got into the same trouble as Mr. Waters with regard to sow pigs. The owner put the hog with them to see if they would breed, but it did not come off. Many pigs castrated, both by himself and other people, had been swollen up behind this year, and they had generally been fed with over-heated barley or wheat, or corn spoiled in last year's bad harvest. In regard to torsion of the womb, he was called to a cow that had been uneasy from 9 a.m. to 9 p.m., but showed no sign of calving. He found she had torsion of the neck of the uterus. He got his fingers into the uterus, tied her legs, rolled her about, and had a man pushing on her body, eventually the uterus twisted round, and they got the calf. He had to go and syringe out the cow, which made a good recovery. Two years ago he went to a Shire mare, due to foal on April 30th. She had been at work, and had made every preparation for foaling, but nothing came forward and she had no pains. She was kept at work till July 25th, when she had decreased in size and lost flesh a little. He was sent for on July 25th and found the foal dead. It had probably been dead two months, and was putrid. He syringed her out, and she made an uneventful recovery. Two years later she died from azoturia. He never knew a mare to carry a dead foal so long. He had made post-mortems on horses from the Fen districts, mostly in poor condition, which had been transferred to highland farms where they were put on corn, and in several cases died off in a few hours; and he frequently found them full of red worms.

Mr. BRAY said he had a case of torsion in a heifer. He got his hand in and felt the grooves of the womb going in a definite twist, but it evidently righted itself suddenly, and he delivered the calf. He thought the heifer was all right, but she collapsed the same night, and as he never saw her again he did not know the cause of death. As to setting fractures, he found ordinary tar rope an excellent thing. He bound it round and round over tow, which enabled him to keep it to the shape of the leg. Last week he had a case of a fractured jaw, and it was a difficult thing to know how to put the splints on. He used a pitch plaster and cut a leather splint to fix it on outside, but the owner got tired of it in three days, though he said it would have to remain five weeks. The animal was shot, and he saw it after death. It was a compound fracture completely across, and exactly at the bend.

The CHAIRMAN said that some members, when speaking of the twisting of the uterus, or torsion, seemed under the impression it was a complete twist, but that was very rare. If it was a complete twist it would be absolutely impossible to untwist. It was a half, or at most a three-quarter twist. If when putting in one's hand the grooves were followed and then a handkerchief was twisted to correspond, it would be found to be a half-turn, but that was quite sufficient to stop a foal coming. He was called to a marsh farm to set the fracture of a cow's leg. He put on a plaster of Paris bandage, strengthened with splints, and although the cow before he put on the bandage ran about on three legs, she put her whole weight on the damaged leg as soon as

he had bandaged it; the whole thing went almost double, and nothing he could do would alter it. In the end the cow had to be destroyed. Detailing a case of quittor, for which he said Mr Shipley's treatment was removal of the cartilage, injections had been tried, but seemed of no use. The animal was cast and they stripped the horn, found the diseased cartilage, removed it, and in scraping out the wound with a curette there was a slip through the tissues into the joint, and at once the wound was flooded with synovia. The wound was flushed with perchloride, plugged with oil of cloves and cotton wool, and bandaged. At the end of three days the bandage was removed and the wound seemed healthy, but there was a little coagulated synovia. It was again bandaged, and at the end of another three days no synovia was found, and the hole seemed to have closed up. The animal made a good recovery, and had no bandage on. He hoped in a day or two it would be turned out to marsh.

Mr. WATERS, replying on the discussion, said he omitted to state in the case of redworm that peritonitis was the ultimate cause of death. The ruptures were so large that there was a quantity of fluid in the peritoneum, which was bound to set up peritonitis. In the case of torsion he would admit it was not a very bad twist, but when a mare had labour pains for 50 hours and no amniotic fluid passed, it went to prove there was a very distinct twist. Fractures in cattle were very easy to set, and it was a great omission if they did not set fractures in the case of bullocks under two years old not fit for slaughter, unless the fracture were compound. He had set nine or ten cases in his small way in the last four years and every one did exceedingly well. The animals might go a little stiff, but that was all, and the owners fattened them. As to spayed sows, he felt rather proud when everybody agreed it was due to heated grain. But the question should be followed up for its physiological interest. He had been asked what the treatment was for Hodgkins disease in the dog. His chief reason for mentioning this was that he wanted to know himself, but apparently the members were unable to tell him. Mr. Little, who examined one of these glands before the meeting, told him that arsenic was the treatment for it, but he did not know whether he would see any more cases to try it. For setting fractures he used to make a pitch plaster of resin and pitch, but now he bought the sticks from the chemist, broke them up, put them into something over the fire to melt, smeared all over the affected limb, and covered it with tow making a thick plaster all over it. He was always careful to have the patient put into a box where there was no straw and only chaff. He once set a three-year-old bullock's fractured metacarpus with plaster and splints, and it did well. Mr. Little mentioned a case of opening the joint in quittor. Seven or eight months ago he was operating on a mare for the same thing, and he was about to make the last cut as the mare was just coming round from the chloroform, when she gave a jerk and the knife slipped through and let out some synovia. He did the same thing as Mr. Little, plugged it with oil of cloves and cotton wool and bandaged it. The accident did not seem to make any difference, and the quittor did far better than if it had not been opened.

Mr. SHIPLEY moved a vote of thanks to Mr. Waters for contributing his interesting paper.

The Hon. SEC. seconded, and Mr. Waters, in reply, said he was very glad his paper had been appreciated.

The Hon. SEC. proposed a vote of thanks to the Chairman who, he said, was in the chair for the first time, and he had conducted the business admirably.

Mr. THURSTON seconded, and the Chairman briefly replied.

ANNUAL REPORT OF VETERINARY SECTION, PUBLIC HEALTH DEPARTMENT, MANCHESTER, 1912. MILK AND TUBERCULOSIS. [ABSTRACT.]

This report forms part of the Report on the Health of the City of Manchester, by James A. Niven, M.A., M.B., LL.D. It is not absorbed and put out of sight as in the reports of a few of the northern cities.

These Manchester cowsheds number 229, on 118 farmsteads, having a total housing capacity for approximately 2,000 cows.

The general standard of cleanliness and supervision has been fairly well maintained, allowing for the ordinary lapses which are bound to occur in any business.

The total number of inspections of City cows during the year was 7,981. A careful enumeration of the cows housed was not made during the year. The last time this was done the total number was found to be 1943. The total will now be somewhat less.

During the past year there have been many factors to disturb the general business of dairying. The price of cows rose to an abnormal height; it would be no exaggeration to say that the cost of good-class dairy cows had risen not less than £3 or £4 per head, and the cost of all foodstuffs had risen correspondingly. The supply of dairy cows was already limited enough to make matters difficult, when the outbreak of foot-and-mouth disease appeared, bringing about an enormous dislocation of trade, and one of our greatest sources of supply was entirely cut off. How serious this has been can only be appreciated by those who come intimately in contact with the dairy farmers, whose business is carried on within the boundaries of the City, for, practically speaking, there is no breeding of cattle within our area. The system in vogue is usually described as the "one note" system, the practice being to buy good cows at the height of profit, milk them as long as the milking period lasts—where cows are left barren the period of lactation is as a general rule considerably prolonged—finally the cow is fattened and sold to the butcher. The conditions are entirely unlike those on country farms. Economically the system is bad. It denudes the bovine population of many excellent animals whose services would be extremely valuable for breeding purposes. On the other hand the system affords considerable protection against tuberculosis, inasmuch as the population is continually being changed and refreshed by carefully-selected, healthy young cows, which, being well housed and well fed, show little tendency to develop disease. But there must be a plentiful supply of the class of cow required, and they must be obtainable at a reasonable price. This has not been the case in the past year, and the result is that many men have been compelled to purchase animals of a class that for years I have done my best to prevent, and I am compelled to accept animals of a class I object to very much.

It will thus be apparent that the necessity for rigid and repeated inspection is greater now than it has been for some years past, and it will be impossible to maintain the high standard of freedom from infection in the milk supply produced at our doors, unless adequate assistance is provided to enable an efficient supervision to be exercised.

During the year, three cases of tuberculosis of the udder were found in the cows within the City. No case was of such a character as to attract the suspicions of the owners. All three cows were killed; two of the carcasses were passed for food, and the third was condemned. In addition, 15 cows were removed from the City because they were, in my opinion, suffering from tuberculosis in one or other of its many forms, other than disease of the udder.

TUBERCULOUS MILK.

During the year, 576 samples of milk have been collected by the Food and Drug Inspectors in connection with tuberculosis. Of this number, 555 were collected at the railway stations, and the remainder from carts coming in by road. The number of farmers represented in the total is 484.

County.	T. Milk.	Per cent.
Caeshire	294	41
Derbyshire	75	3
Staffordshire	49	5
Lancashire	50	3
Shropshire	3	1
Yorkshire	10	1

Westmorland, Lincolnshire, and Wiltshire one each, and none of these sent tuberculous milk.

Table showing number of farmers' milk tested during the year, and the number found to cause tuberculosis in the experimental animals.

Year.	Tested.	Tuber- culous.	Year.	Tested.	Tuber- culous.
1901	272	27	1908	289	27
1902	345	36	1909	535	31
1903	329	45	1910	468	30
1904	318	29	1911	494	51
1905	565	47	1912	484	54
1906	542	42			
1907	562	38	Total	5203	457

The percentage of farmers sending tuberculous milk was 11.15, the highest figure during the past 12 years, with the exception of the year 1903. In fact since the 1909, when we reached our lowest figure (5.79 per cent.) the rise has been extraordinary; the most marked rise being in the figures for the year 1911.

The continued rise is disturbing, and, as far as I can see, very difficult of explanation.

I ventured in last year's report to suggest that the summer of 1910 had had disastrous effects upon the health of cattle, inasmuch as they were all subjected more or less to conditions of insufficiency of food, and much of the food available was of inferior quality, so far as its nutrient properties were concerned. Despite many statements to the contrary, I am still of opinion that the results of that season were far more serious than many may suppose, and that they will be felt for some time to come.

If the rise so marked during the past two years in the amount of tuberculous milk, and, presumably, the amount of bovine tuberculosis, were due solely to the relaxation of vigilance on the part of the stock-keeper, it would not be difficult for men experienced in the inspection of cattle, and in the assessment of the character of the individuals concerned, to detect some evidence of it on the farms. So far I find no evidence at all to justify any such accusation, indeed I may say that I have only seen one really well-marked case of tuberculosis of the udder during the whole year. The general condition of the cattle is apparently good, and, in most cases, even to the skilled observer, a careful examination of the cows at pasture would show nothing. I note that such a shrewd observer as Prof. Delpeine, whose opinion on these matters has to be treated with the greatest respect, is inclined to think that what may be termed the period of retrogression is due in some part to the carelessness of farmers, induced by the promise of protective legislation, or, rather, legislation which appears protective—the promise to pay compensation for diseased animals. I wish I could agree to this supposition; it would be a very simple explanation, and would merely require for its determination a strengthening of the measures in force. Un-

fortunately, the actual evidence which I have obtained is that they do not welcome legislation at all, and if the experiences gained immediately prior to the Tuberculosis Order, 1913, coming into force are any indication of the attitude of the dairy farmers, then the conclusion forced upon one is the exact opposite. For the six months prior to this enactment coming into effect, cows to which the very slightest suspicion could be directed, were being removed from very many farms. The farmer seldom, or never, welcomes the inquisitorial inspector, be he medical, veterinary, or police, but he would much rather see either of the first two on his farm than the latter.

Where actually the true cause for the increase lies is impossible to say, but one may draw deductions by some facts made evident by an examination of the material at hand. In the first place, I have been carefully examining the records of the past years, and I find no year in which so many very young cows were found suffering tuberculosis of the udder. Of the 44 cows found during the year suffering from tubercular disease of the udder, no less than 16 had had not more than two calves, and of these nine were heifers which had only had one calf. The last figure is particularly striking, for, so far as our previous records are concerned, in no three years have we had as many young animals in the first lactation period proved to be suffering from disease of the udder.

I cannot admit that there has ever been any less care taken in the examination of heifers than aged cows on the grounds that the young animals are less likely to be the subject of disease of the udder than older animals. Less time is required for the examination it is true, as the udder is only small and partially developed; but even slight lesions are much more easily detected, and I have always regarded the careful inspection of the recruits as a matter of the highest importance.

Most young bovines commence the duties of maternity long before maturity, and, as a matter of actual practical experience, all other things being equal, if the highest milking powers are to be developed, the function of calf-bearing must not be unduly delayed, and, as will also be evident, it is essential that milking cattle should be brought into profit as soon as is compatible with sound principles of dairying.

On the other hand, if these young animals have to suffer during their period of adolescence from lack of good food, and live on the great majority of farms, in infective surroundings—for no greater indictment could be brought against farmers than the awful conditions which too frequently surround the rearing of calves—then it would appear that every essential has been provided for the unrestricted development of tuberculosis in the young animals.

It may be that there are many other factors of which we are not cognisant which play an important part in the rise in the amount of tuberculosis. As I have already stated, I have seen no evidence of neglect, nor are there many "wasters" about, but I have certainly had the impression that latterly there have been more cases of suspicious conditions simulating tuberculosis, the pulmonary lesions being, as usual, most marked.

Another factor which may also play an important part, is the indiscriminate slaughter of young calves in such enormous numbers for veal. I do not refer to it in regard to their fitness for slaughter, or otherwise, but from the economic standpoint that such wholesale slaughter in dairy districts is not sound policy. I know that it will be stated immediately that calf-rearing is not profitable. With that I have nothing to do, but to point out that a very large percentage of the female calves slaughtered are the offspring of excellent dairy animals of a reasonably good milking capacity, and such as would most probably grow up into good useful dairy animals themselves. The effects of this policy will be felt by the farmers themselves, even if it

is not being felt now. I have referred in the earlier portion of my report to the abnormally high price of stock for the past two years. I don't think that an abnormally increased demand is much responsible as the fact that the supply is inadequate, and, in my opinion, nothing could be more disastrous than a shortage of good, well-bred, healthy young stock to replenish herds frequently; in fact, the supply should exceed the demand to produce the ideal conditions.

During the year 44 cows were found to be suffering from tuberculosis of the udder, and of these 43 were slaughtered. Of these the carcasses of eight were passed as fit for food, four partially, and the remaining 31 were condemned as unfit for food.

Eleven notifications were received during the year, but in not a single case was the subject of notification found to be suffering from tuberculosis of the udder. In nine cases, however, the cows were found to be suffering from pulmonary tuberculosis, and were slaughtered, and in every case the diagnosis was confirmed at post-mortem.

It should be stated that the diagnosis of early tuberculosis of the udder presents increasing difficulties, requiring the very greatest care in the manipulation of the udder itself. The discovery of the tubercle bacillus microscopically in such a high percentage of our cases by Professor Delépine has been of the greatest value both to the farmers concerned, to whom the saving of time means a considerable saving of money, and also to us, as it has enabled us to dispose finally of our cases much more quickly than was formerly the case.

One case occurred during the year which illustrated some of the difficulties in finding the actual cow producing the infective milk. A sample of mixed milk was taken in the usual way at the railway station, and was reported by Professor Delépine as having been found to cause tuberculosis in the inoculated animals. The farm was visited by me, and 46 cows were carefully examined. The herd was an excellent one, the cows, without exception, being all big, fine, healthy-looking animals, with no appearance of disease among them.

I found one cow presenting a very slight lesion of no decided character in one quarter of her udder, and from this cow a sample was obtained; and I also took a sample of milk from a cow which presented a somewhat irregular udder, with no definite lesion. Both these samples were submitted to the biological test by Prof. Delépine, and he reported both as negative.

In the meantime a further mixed sample was obtained and submitted for examination, and again Professor Delépine reported that the mixed milk was tuberculous. I again visited the farm, and could find still no evidence, except the cow first referred to; she had been moved to another stall in the cowshed, and this time the lesion appeared most prominent in another quarter, so a sample was taken from this quarter, and submitted again for examination, and again with negative results. On this occasion I took a mixed control from the whole herd myself, as there was just a possibility that, owing to there being so many others of the same name in the district, a mistake in the identity of the farm had been made. That this was not so was proved when Prof. Delépine reported my control same to be tuberculous.

I therefore again visited the farm, and on this occasion divided the whole herd into nine groups, and took a mixed sample from each, and each of these nine group controls was found free from infection; but in the interval between this last visit and the previous one the roan cow from which I had already taken two samples had been sold. That no other cow had been sold I was quite certain, because I had the whole herd under observation so much that I could have told almost to a certainty if any cow had been changed, and, further, during the greater part of the time this investigation was being carried out, the Prohibition of Movement

Order was in force on account of some outbreaks of foot-and-mouth disease in the area.

It is remarkable that all the mixed samples taken while this particular cow was in the herd should prove tuberculous, and that the infection should cease immediately she was removed; and yet the two special samples taken direct from her yielded no result. Further mixed samples taken from the milk supplied from this farm remain free from infection. It was unfortunate that we lost sight of this cow, but it was not possible to make the farmer keep her, however interesting she might have proved scientifically; the financial aspect appealed to him, and he could see that she was the only cow in the herd of which I had the slightest suspicion.

The total number of country cows examined during the year is 3203. From the particulars supplied by the farmers, 399 of whom replied to our queries, we find that on these farms there were 7975 cows, or an average of 19.98 cows per farm; or if the general figures are averaged, it will be found that the milk of nearly 10,000 cows was tested during the year.

I should again like to place on record the valuable assistance rendered to Manchester by Dr. Meredith Young, the Medical Officer for the County of Chester. His activity in the work of improving the conditions of cattle housing in the County is unabated.

Tuberculin Test.

The table attached shows the results from October, 1904, to November, 1912, obtained in keeping a large herd free from tuberculosis. The work is an unqualified success. The development of the practice of rearing young stock sufficient to replenish the herd, is being pushed on. The results are most encouraging, the young stock have done well, and we shall soon have sufficient to be entirely self-supporting. The milk produced by this herd is supplied to Monsall Fever Hospital, Clayton Hospital, and Baguley Sanatorium.

Salvarsan in the Horse and Dog.

J. D. E. Holmes reports ("Memoirs of the Department of Agriculture in India, 1913." Vol. I. No. 2), his experiences in the treatment of surra in the horse and dog by salvarsan.

They are summarised as follows in *The Tropical Veterinary Bulletin*.

HORSE. In preliminary experiments the toxic dose by intravenous injection was ascertained approximately, and the effects of both small and full subtoxic doses were gauged by the period for which the peripheral circulation remained free from trypanosomes after treatment.

In the first series of experiments 17 animals were given a single dose of the drug. Of these, 3 recovered, 11 had relapses, and 3 died. The dose administered varied from '0014 to '0094 grammes per pound body-weight.

In the second series of experiments three injections were given at intervals of one day. Only two animals were treated in this manner; in one there was a relapse and the other remained under observation for ten months without a reappearance of the trypanosomes being recorded.

Two animals received three injections at intervals of one week. In both cases there was a relapse. Four animals were given, in addition to the three injections of salvarsan, one dose of arsenic *in bolus*, the dose being one gramme. In none of these was a cure effected.

The author's conclusions may be summarised as follows:—

(1) The toxic dose of salvarsan for the horse administered intravenously is approximately '01 gramme per

pound body-weight, but individual susceptibility exists.

(2) An intravenous injection of salvarsan is followed by a disappearance of trypanosomes from the peripheral circulation for periods varying from 6 to 36 days. The relationship between the dose of the drug, and the period of absence of the trypanosomes is neither regular nor definite.

(3) In three cases a single dose effected a cure.

(4) By repeated administration a tolerance to the drug is established.

(5) Three intravenous injections did not give results superior to those obtained by a single injection.

(6) The administration of a large dose of arsenious oxide followed 24 hours later by an intravenous injection of salvarsan produced no better results than a single dose of either.

DOG. The difficulties in the way of treating dogs for surra lie in the facts that the dog is particularly susceptible to the disease, and also very intolerant of the drugs which have given the most encouraging results in other species.

Twenty-nine dogs were given a single injection of salvarsan in doses varying from '006 to '063 grammes per pound body-weight.

Of these two remained under observation for 370 days without a relapse. Eleven died in periods varying from a day to several weeks after treatment, but for the most part trypanosomes were absent from the circulation during that time. In four cases there were relapses, and the remainder of the dogs had to be destroyed owing to their having come into contact with a dog suspected of rabies.

In all these cases the drug was administered in an 0.5 per cent. solution.

In six instances the drug was used in a 1 in 250 solution, but all the dogs died within 48 hours after the injections were given.

Six dogs received injections at intervals of a day, but either death or relapse occurred in each case.

Of two dogs which received three injections at intervals of a week one recovered and one died. Similar results attended the experiments when only two injections were given at a similar interval.

Three dogs were given a single subcutaneous injection, but none recovered. It was found that subcutaneous injection produced painful swellings which either burst or were absorbed.

Intramuscular injection proved successful in one case and failed in another.

The following conclusions are drawn :—

(1) The toxic dose of salvarsan for the dog is about .025 gramme per pound body-weight, and .02 gramme is fairly well tolerated. More dilute solutions produce more markedly toxic symptoms than more concentrated ones.

(2) An intravenous injection may cause the disappearance of the trypanosomes from the circulation for periods varying from 20 to 97 days.

(3) Repeated injections do not give better results than a single administration of the drug.

(4) Subcutaneous and intramuscular injections are not well borne. Three rabbits which were given doses of .000042 to .000064 gramme all recovered.

[Surra does not immediately concern English practitioners, but some portion of this work upon salvarsan is capable of a wider application.—Ed.]

ANNUAL REPORT OF THE CIVIL VETERINARY DEPARTMENT UNITED PROVINCES, 1912-13. [ABSTRACT].

Mr. E. W. Oliver held charge of the department up to Feb. 21st, 1913, when he proceeded on leave. He also carried out the duties of Second Superintendent in addition to his own work from April 19th to Oct. 20th during the absence of Mr. C. W. Wilson on leave.

Mr. C. W. Wilson carried out the duties of Second Superintendent from April 1st to 18th, and from Oct. 21st to the end of the year. He also officiated as Superintendent from Feb. 21st, 1913, to the end of the year in addition to his own duties.

Mr. Oliver was on Tour for 133 days and travelled 555 miles by road and 18,268 miles by rail. He toured in 21 districts supervising the work of the veterinary inspectors and the district board veterinary assistants. Nearly all the veterinary hospitals and dispensaries were visited and sites for the erection of others were selected, while a great deal of travelling was undertaken to inspect various stallion stands and stud bulls maintained by local bodies and others. It was often found necessary to visit and spend some time at the Moradabad stallion depot for inspection and selection of sires for district work, and constant supervision of the bull-rearing farm at Lakhimpur has entailed a great deal of travelling. Land for another cattle farm at Madhuri Kund in Muttra district has also been surveyed with the object of acquiring a suitable site for this purpose. Much touring has, as usual, been found necessary in connection with the Glanders, Farcy, Surra, and Dourine Acts, and in supervising sheep breeding operations in various localities. Mr. Oliver personally attended and carried out investigation and research in twenty outbreaks of disease, and wherever possible directed inoculations and treatment. He visited Bombay for the purchase of stallions and inspected various tonga lines in the provinces. During these tours district officers, landowners, managers of courts of wards, and others interested in agricultural stock were met and

conferred with, and meetings of committees dealing with the question of improving the conditions of dairy produce were attended and expert advice given.

Mr. C. W. Wilson was on tour for 82 days during which time he toured in 24 districts and travelled 6678 miles by rail and 350 miles by road. He inspected the majority of the hospitals and dispensaries in his circle, all the stallion stands, and attended cattle fairs at Ballia, Dewa, Khairabad, Sardhwa, Attarra, Etawah, Hardoi, and Saharanpur acting as judge or member of committee. He inspected stud bulls the property of courts of wards, and advised special managers regarding cattle breeding and maintenance of stud animals. He personally attended outbreaks of cattle disease in 13 districts, and supervised the inoculation work. A considerable amount of his time was spent in checking inoculation returns, specially in those districts where opposition to inoculation had previously been met with. He was deputed to select for district boards, court of wards, and private persons, stud bulls from the Hissar cattle farm. The sheep flocks in his circle were inspected and advice given to those in whose hands the care of the flocks is entrusted. He attended the outbreak of foot-and-mouth disease at the Manjhra cattle farm and paid periodical visits of inspections. He personally accompanied the foot-and-mouth disease enquiry commission to village Manaura in the Jalaun district to demonstrate disease *in situ*, and attended the examinations of final year students at Punjab Veterinary College, Lahore, as a member of the board of examiners.

Veterinary Instruction. The veterinary colleges now provide for their students a suitable training in inoculation, etc., and these men on entering this department are, as opportunity occurs, deputed to districts under the supervision of an inspector where actual outbreaks of diseases exist, in order that they may acquire a working knowledge of inoculation methods as conducted in the field. A course of practical demonstration in pathology and bacteriology can be obtained now at the headquarter laboratory in Lucknow by young veterinary assistants, and these men before being drafted to a district have acquired a knowledge of laboratory methods essential to those working in the field.

It is regrettable that the offer of scholarships still fails to attract suitable young men of these provinces to the veterinary profession. The reason for this seems to be the natural disinclination of the young men in these provinces for any sort of practical work amongst domesticated animals. Last year it was suggested that if this state of things continued it would be advisable to throw open the scholarships to suitable men, residents of the Punjab and other allied provinces. His Honour the Lieut. Governor however was of opinion that no recourse should be made to this if it could be possibly avoided. After several years' trial the danger of the inadequate number of graduates for the department remains imminent.

Treatment of Disease. During the year under report 75,571 cases of contagious disease have been notified from practically all districts in the province with a reported mortality of 24,602. Rinderpest, as usual, has been the most serious and has accounted for 17,363 of the deaths reported. With the increasing attention given to and facilities for ascertaining details and reporting outbreaks, many more now-a-days come to light than in past years, and it is highly probable that only now approximately accurate estimates of the amount of contagious disease with its consequent annual mortality are being obtained.

Glanders and Farcy.—Thirty-eight animals either succumbed to the malady or were destroyed in accordance with the Glanders and Farcy Act. The disease

assumed a severe form on the Dehra Dun-Chakrata Road and also on the Kathgodam-Ranikhet Road, which is often the case when the disease occurs on tonga routes and those places where there is much equine traffic. A scheme has been introduced for the granting of compensation for compulsory slaughter of animals under this Act with a view of bringing to light suspicious cases which would otherwise not be reported.

Surra.—Very few cases of this disease have been discovered during the year. This is attributed to the great scarcity of certain blood-sucking flies (probably tabanus, tropicus, and others) which generally make their appearance annually at the "surra season." Those animals which last year were subjected to the arsenic treatment for this disease are still living and healthy. It is considered that this treatment, although difficult and expensive to apply in the field, may now be regarded as specific in a high percentage of cases.

Dourine.—Five fresh cases of this disease were brought to light during the year and dealt with under the Dourine Act. Suspected animals were traced, registered, and put under observation.

Tetanus.—Eighty-two cases have been reported by veterinary assistants from 18 districts, and 48 cases proved fatal.

Strangles.—One hundred and twenty-six cases of this disease were treated by veterinary assistants, out of which 15 proved fatal.

Epizootic Lymphangitis.—No case was reported.

Other Contagious Diseases.—Under this heading cases of horse-pox, piropasmosis, influenza, anthrax, rabies, as well as those diseases caused by internal and external parasites have been met with, but up to the present it has not been found practicable to introduce a reliable system for obtaining returns.

Rinderpest.—This year very few districts altogether escaped its ravages, although many were affected by a benign form which was quickly suppressed. A very virulent type existed in the districts south of the Nepal forests, from whence it is believed to have extended into British India. The infection was probably brought by the cattle which annually migrate to those jungle tracts for the grazing. Owing to the almost wild nature of these herds a rapid spread of the disease ensues, and as they are untractable except in mobs or with the aid of the lasso it is difficult to apply those measures for its stamping out which are used when dealing with the ordinary domesticated cattle. Where the district board's veterinary staff was insufficient, provincial veterinary assistants from the headquarter staff were deputed and rendered the much-needed assistance. Inoculations were carried out in 37 districts. In the Jalaun district alone 9,115 cattle were immunised.

Hæmorrhagic Septicæmia.—This year appeared in 38 districts with a total mortality of 1962 as against 3679 of last year; 12,667 cattle were inoculated with generally satisfactory results.

Black-quarter.—This malady appeared in 17 districts, and 1105 deaths are reported from Jhansi district alone 288 animals are reported to have died. It causes considerable losses amongst young stock, and in certain localities in which it recurs periodically. Cattle were vaccinated as a preventive measure. There is good reason to believe that much saving of stock could be effected if systematic vaccination could be carried out in those places where black quarter appears annually, providing this could be done before the customary time for its appearance has arrived. At the present time this is impossible owing to the insufficient staff of district board veterinary assistants.

Anthrax.—Reports of this disease were received from 34 districts and 1580 animals perished. It is not easily diagnosed by laymen and consequently often confused with other diseases. Hence very little reliability can be

placed on these figures. Notification of anthrax cases is always given to the American Consul.

Foot and Mouth Disease.—This affection has been very widespread, and has appeared with varying intensity throughout these provinces, very few districts escaping. The reported losses from the disease were 1626, the mortality being chiefly confined to young stock or old decrepit animals. It causes much inconvenience to agriculturists, especially during the harvest or ploughing season. Cattle fairs and markets are responsible for much of the spread of the disease, and the appearance of one case in a village is often soon followed by general infection throughout the whole of the village cattle. This is to a great extent owing to the apathy and ignorance of the villagers themselves, who cannot be induced to realise the necessity of early treatment, segregation, etc. The veterinary assistants have been kept very busy throughout the year in attending and treating cases of this disease. Where funds were available medicines have been distributed free to owners of affected cattle. A special commission on foot-and-mouth disease from England to study the disease *in situ*, assistance has been rendered by this department during their enquiry and morbid material procured for them.

Other Contagious Diseases. One hundred and thirty two head of cattle are reported as having died from other contagious diseases, which include pleuro-pneumonia, tuberculosis, and contagious abortion.

Preventive Inoculation.—Protective inoculations, chiefly against rinderpest, have been carried out on a very large scale. Operations of this nature were undertaken in 892 outbreaks against 397 in the previous year, and 62,435 animals have been inoculated during the year under report. Subsequent enquiries attest that results have been highly satisfactory. Very little opposition is now encountered, the beneficial consequence of the practice gradually overcoming the prejudices of the people.

Other Diseases. The veterinary assistants visited 19,691 villages against 19,786 in the previous year, and treated 45,687 animals or other contagious diseases than those already reported on. Although from this it would seem that this particular branch of work continues satisfactory, still the opinion is held that when contagious disease is not prevailing, these men could be more usefully employed at dispensaries, if more were established at headquarters, than in touring about the country looking for isolated cases to treat.

Investigation of Disease. During the year under report specimens of blood, morbid tissues, intestinal and other parasites have been submitted to the new laboratory at headquarters by veterinary inspectors, assistants, and also from district authorities for bacteriological and pathological investigation and opinion. Animals affected with various obscure diseases have also been sent for investigation, but owing to lack of accommodation much useful material has had to be refused since there was no place to keep them in. Owing to the development of the department and the increasing interest shown by the public in its endeavours to mitigate animal disease, it has become necessary to devote more attention than formerly to that branch of work which includes research. Such diseases as kamri, barsati, akrab, dourine, pleuro-pneumonia of goats, fowl spirochaetosis, malignant jaundice (piropasmosis) of the dog, as they occur in India, all call for more accurate knowledge, and at such a place as it is proposed to establish, work in this direction could be carried out with much benefit. Sanction has now been accorded for the erection of a suitable building in Lucknow.

Cattle Poisoning. Cases of criminal cattle poisoning have been reported from six districts. These were

investigated and handed over to the police to deal with.

Veterinary Hospitals and Dispensaries. There are now 46 hospitals or dispensaries in working order in the province. Those large and well equipped institutions in the important cities and towns, with adequate accommodation for in-patients are classed as hospitals while the less important ones of limited accommodation come under the head of dispensaries.

It is satisfactory an encouraging to record that the total number of cases treated during the year at hospitals and dispensaries was: out-patients 43,106 and in-patients 4061, making a total of 47,167, an increase of 6775 on last year's return. Some districts have introduced the system of charging a small scale of fees to those owners who can afford to pay, whilst others are as yet averse to the procedure. Where the system has been adopted and carried out in a business-like way it has proved a success, and has in no way affected the popularity of the hospitals. In Lucknow, the hospital has brought in an income of Rs. 2593 during the year, and has an average daily attendance of four new cases.

Breeding Operations. Stud Bulls. The provision of adequate bull power appears to be giving a considerable impetus to the cattle breeding industry which year by year is arousing greater interest in the minds of the public of the province. The endeavours of the Civil Veterinary Department have been directed towards the production of—

(a) Improved working bullocks for ploughs, wells, and general agricultural purposes as well as for heavy draught work.

(b) A higher milk yielding class of cows.

For the latter purpose a further batch of 13 bulls of the Hissar breed was obtained from Government Cattle Farm, Hissar, this year, and issued where required.

The bull rearing farm at Kheri is now in working order and continues to progress satisfactorily. Arrangements are being made to clear all the jungle, and it is hoped within a few years to convert the whole 500 acres into first class grazing land. There is at present 268 head of young stock on the farm. As anticipated last year, it has been possible to issue 25 good young stud animals in 1912 which is much earlier than the original scheme provided for, and a further batch of 26 will be ready in May, and again during the cold weather of 1913.

As the Hissar Cattle Farm has now passed under the control of the Punjab Government, and since everything points to a still greater demand for the heavier breeds of bulls such as Hissar, Kosi, etc., for the western districts of this province, as well as for improvement in the breed of milch cattle, a scheme has been submitted for establishing another farm in the Muttra district for breeding suitable animals.

Horse and Pony Stallions. At the beginning of the year under report there were 56 stallions on the register, all being the property of the provincial government.

Six stallions were purchased by the department during the year, four were castrated and sold, as they were considered unfit for further stud purpose, one died from snake bite, thus leaving a balance of 57 at the end of the year. Forty-eight stallions were employed at stud.

The number of mares covered by these stallions has amounted to 2,759; an increase of 20 on the previous year's coverings.

It is satisfactory to note the decided improvement and promise shown by the young stock, progeny of these provincial stallions in many places. Some exceptionally good young stock was noticed at the Saharanpur fair. The Arabs "Bumblepuppy," "Sardar," "Copenhagen," and "Brigand," all of which are very popular with the breeders, have maintained their high standard and reputation as prime foal getters.

The functions of this department in so far as horse breeding is concerned, are confined to the improvement of the indigenous horse and pony for the general utility of the people in those tracts other than the four selected districts of Aligarh, Muzaffarnagar, Bulandshahr, and Meerut, and it is noticeable that these tracts which were primarily considered unsuitable for horse breeding are now proving themselves capable of producing an animal which may be confidently expected to further improve.

Donkey Stallions.—There appears to be still an increasing demand for the services of donkey stallions for mule breeding, but the limited number available renders it difficult to meet the demand. It has been found impossible to obtain donkey stallions suitable for the purpose in India, therefore it is essential to think about making some arrangements for importing them if the mule breeding industry is to be encouraged and sustained.

Sheep Breeding.—Operations have been started in this direction as was proposed last year with the object of ascertaining if there is any possibility of improving the quality and quantity of the wool of the Indian sheep. Experimental flocks have been formed and located at Aligarh, Moradabad, Bahraich, Kheri, Allahabad, Banda, Partabgarh, and Lucknow, and imported Merino rams introduced into the flocks. Already some 55 half-bred Merino lambs have been born, but as yet it is too early to give any opinion in the matter. For this experiment 12 Merino rams were purchased, and during the year there were four casualties.

Fairs and Shows.—Temporary veterinary dispensaries were opened in connection with the Etawah, Bulandshahr, Saharanpur, and Batesar fairs under charge of District Board or Municipal veterinary assistants. Interesting specimens of drugs, instruments, etc., dealing with treatment of agricultural stock were on view at the Etawah Exhibition, and demonstrations in inoculations and other methods were given.

Rupees 1401 were contributed towards prize awards, and this amount was distributed at Saharanpur, Bulandshahr, Banda, and Ballia fairs.

Subordinate Establishment.—During the year the subordinate staff has increased from 156 to 162, and the strength of the establishment as it stood on 31st March was as follows:—Veterinary inspectors 16, veterinary assistants employed by Districts Boards 118, by Municipalities 15, by the Society for the Prevention of Cruelty to Animals 1, and 12 belonging to the provincial or headquarters staff (including one at the Cawnpore Agricultural College). One veterinary assistant was dismissed by the District Board, Etawah, for falsifying inoculation returns, and another of Naini Tal District Board for perjury.

Although the staff has increased considerably since the re-organisation of the department in 1903, when there were three inspectors and 51 assistants, it is still far below the requirements. In 1907 it was considered that one veterinary assistant per tahsil was needed and should be employed, but even now provision for that number has not been reached. The Superintendent is of opinion that not less than two men per tahsil can ever successfully cope with the amount of work connected with the treatment and preservation of agricultural and other stock. District Boards, either from want of funds or because they fail to realise the urgency of providing veterinary help for the agriculturist whose welfare depends so largely on cattle, are still reluctant or adverse to make an increase in their veterinary staff. The Dehra Dun district comprising an area of 1193 square miles of very difficult country, with a cattle census of 248,679 and those cattle possessing a high degree of susceptibility to contagious disease, is naturally continually visited by outbreaks of cattle disease, yet up until February last the District Board maintained

but one veterinary assistant to deal not only with contagious disease but also to carry out the ordinary duties expected of a veterinary assistant, over that vast area.

The veterinary inspectors are doing useful work and have been busily employed during the year in checking the work of veterinary assistants, conducting inoculation campaigns and other measures to suppress outbreaks, in inspecting and in supervising. The provincial staff of veterinary assistants has done good work in relieving District Board veterinary assistants proceeding on leave and in rendering assistance in treatment of cattle disease and inoculation in cases where the local staff has been inadequate. They also help considerably in making special investigations and enquiries regarding diseases, and some have been able to render good service connected with horse and cattle breeding operations, and in the laboratory. It is found that as a rule the work of these provincial men is of a more efficient and thorough character than that done by those men employed by District Boards under whose orders they are. It is obviously impossible for a District Board to efficiently control officers carrying out work of a technical nature such as this, and hence their veterinary assistants can easily evade duties which they would otherwise find difficult if placed more directly under the control and orders of the Superintendents of the Civil Veterinary Department.

Expenditure.—The cost of the department according to the statement furnished by the Accountant-General, shows a decrease, viz., Rs. 82,724 this year against Rs. 93,938 expended last year.

C. W. WILSON, M.R.C.V.S.,
Officiating Superintendent, C.V.D., United Provinces.

Cruelty to Lambs—Rickets. Dismissed.

At Mistle on Monday, September 1st, before Dr. W. H. Slimon, and other Magistrates, John Bird, farmer, of Ardleigh and Lexden, was summoned for causing unnecessary suffering to four lambs at Ardleigh, between 1st and 18th August.

Inspector Patrick Dooner, R.S.P.C.A., said he accompanied P.C. Link to a field belonging to the defendant, where he saw four lambs in a very emaciated condition, and all lame. One animal had the use of the front legs only, and showed signs of having been dragged along for some considerable distance. Another animal could only walk a little. There were no signs of food or water having been given the animals.

William Norfolk, a shepherd employed by the defendant, who appeared on subpoena, stated that one of the lambs had never been able to stand on its legs. If the animal had been his he should have long since destroyed it.

In reply to the defendant, witness said he had never known him to be cruel to any animal, and he had always supplied more than enough food.

Mr. Walter George Green, M.R.C.V.S., Colchester, testified to examining four lambs which were about four months old. One was completely paralysed, and was dragging its hind on the ground. There were abrasions of both knees through having to crawl. The second lamb was lame, and the off fore-leg was very much deformed. There were abrasions on the knees of both hind legs. The third lamb was suffering from bony enlargement of both knees. The fourth, although lame, was not so bad, but like the others it was suffering from rickets. The legs of one of the lambs were twisted like chair legs.

Defendant called his son, Horace Charles Bird, farmer, of Ardleigh, who said the condition of the animals was caused through over-feeding. Both he and his father were always kind to animals.

The shepherd, recalled, said that, acting on instructions of the Inspector, he killed two lambs. He gave the carcass of one of the animals to the dogs, and that of the other to his neighbour for human food. (Laughter.)

Defendant said he had seen dozens of rickety lambs at lamb sales and markets, and he did not think it was cruelty to keep them.

The Chairman said the Bench were equally divided as to whether the defendant were guilty or not, and the case would therefore be dismissed. He added that he had all his life dealt with cases of rickets, and he knew that to leave lambs in a field to feed by themselves would be cruelty.—*East Anglian Daily Times.*

New Abattoir for Belfast.

The splendid abattoir opened just now is the finest and best equipped establishment of its kind in Ireland, and if Glasgow and Edinburgh did not block the way, we should say of the United Kingdom. There is lairage accommodation for 300 cattle, 1000 sheep, and 200 pigs. The railway facilities are of the best; live stock are brought alongside, and the Board of Agriculture have provided sidings where the inspection before slaughter can be made instead of at the different railway stations, as was previously the case. From a practical, as well as a humane, point of view, this is a most desirable arrangement.

The slaughtering accommodation for all classes of stock is ample, complete, and up-to-date in every detail. The buildings are lighted throughout by electricity, each one has its electric clock, and all are in touch with the inspector's room by means of the telephone. The abattoir covers a space of three and a half acres, and there is plenty of room for expansion.

The offices of Mr. J. A. Jordan, the well-known City Veterinarian and Superintendent of Abattoirs, and his staff, situate at the main entrance, are ideal for their purpose. Meat inspection in Belfast has no dread for the butcher; he has learned by experience that in the very practical hands of Mr. Jordan his interests are not overlooked. Nothing is condemned merely to pander to a fad, the consequence being that our Ulster friends are immune from many of the harassing and vexatious seizures of which we too often hear elsewhere.—*Meat Trades' Journal.*

The Cost of Foot-and-Mouth in Ireland.

The report of the Department of Agriculture and Technical Instruction for Ireland on proceedings under the Diseases of Animals Acts for 1912 has been issued. It deals with the outbreaks of foot-and-mouth disease in 1912, of which there were sixty-eight cases among cattle, one among sheep, and two among swine. The disease had not been previously known in Ireland for twenty-eight years. The total number of animals slaughtered during the operations against the disease, including both infected animals and those in contact therewith or otherwise exposed to infection, was 3592, of which 1928 were cattle, 1533 sheep, 100 pigs, and 31 goats. The aggregate amount paid as compensation for the stock so slaughtered was £28,030 13s. Owing to the restrictions adopted for the suppression of the disease, the exports of cattle, sheep, and swine fell to an unusually low level, the total for 1912 being 1,439,538, as compared with 1,695,039 in 1911. The falling off was, however, almost entirely in classes other than fat cattle, the fat cattle shipments being some 67,000 head in excess of those for 1912.—*N.B.A.*

Cattle Hides Injured by Ticks.*

According to figures gathered by one of the veterinary inspectors of the Bureau of Animal Industry, the presence of the tick among the cattle of the south not only lessens the value of the cattle on the hoof, but causes the hides that have been infested with ticks to be graded No. 4 quality.

The same hides, if free from tick marks, would grade No. 2. The difference in price between these two grades is 3 cents per pound. As the hide of southern steers weighs about 42 pounds, the presence of the tick in the hide causes a loss in the hide alone more than 1.26 dols. (say 5s.) per hide. Government specialists point out that the cost of tick eradication is only about 50 cents per head, so that if the counties make a systematic campaign to eradicate the tick, the increase in value of the hide alone would pay for the cost of tick eradication and leave the farmer a net profit of about 76 cents (3s.) per hide.

A prominent tanner in Pennsylvania states:—"For the class of leather we make we prefer southern hides for chrome, on account of the close texture and fine grain, but on account of the ticks we have had to practically stop purchasing southern hides."

A large percentage of the chrome leather now produced is finished with the grain left on so that all imperfections and tick marks on the grain side show very plainly. In the old days when all the leather for uppers was made from bark-tanned stock, all leather was buffed and the grain was removed, and tanners could use cheap hides that were covered with imperfections and tick marks, and make fairly good leather. The situation today is very different, as the public is demanding more and more grained leathers for which large proportions of southern hides will not be available until the tick is eradicated.

Tennessee will probably be the first State to be entirely free from quarantine for ticks. It already has eradicated the tick in fifty-one counties, and it is hoped that by September 1st the remaining eight counties will be free from ticks and the entire State out of quarantine.

According to the specialists of the Department of Agriculture, it has cost less than 50 cents per head to eradicate the tick in Tennessee, and the cattle owners as a result have gained not less than 7 dols. per head of their stock, so that the investment paid for itself nearly 14 times over in a very short time. This does not include the additional profits which come from the fact that now that the tick is eradicated more cattle can be raised on each farm and the consequent increase of the amount of fertilizer available.

* Office of Information, U.S. Department of Agriculture.

Holstein Bulls for Dairy Herds.

Several of the large dairy farmers in Cheshire are purchasing Holstein bulls for the improvement of the milking qualities of their Shorthorn herds. Mr. W. Carter, Broad Lane, Nantwich, one of the Cheshire County Council small-holders, has a herd of sixteen of these cattle. Recently one of his cows gave 88½ lb., or nearly 9 gallons of milk, in one day. The average yield of Holstein cattle is from 5 to 6 gallons per day. At the South Cheshire Show Mr. Carter showed two of his British Holstein cattle. One of them, Hedges Burnie, won the special prize offered by Messrs. Henry Manley and Sons for the best dairy cow in the show. The same animal also won the second prize in a strong class against all Shorthorns. The other animal, Willow Crewna, a two-year-old heifer, was awarded third, also in a good class of Shorthorns.—*L. S. J.*

Personal.**HIGH COMMISSIONER'S NOTICE No. 66 of 1912.**

It is hereby notified for general information that His Excellency the High Commissioner has been pleased to appoint WILLIAM ALEXANDER ELDER, Esq., M.R.C.V.S., Veterinary Officer to the Swaziland Administration, to be a Justice of the Peace for the Territory of Swaziland.

By command of H.E. the High Commissioner.

C. H. RODWELL, Imperial Secretary.

Pretoria, Nov. 11, 1912.

Mr. W. GRAHAM GILLAM, M.R.C.V.S., of Prince Albert, late of Minehead, Somerset, was one of the judges at the Agricultural Shows at Melfort and Prince Albert, in the Province of Saskatchewan.

Mr R. M. MALLOCH, M.R.C.V.S., Kirkby Stephen, has been appointed foreman of the jury in the enquiry on the Aisgill railway disaster.

COMPULSORY NOTIFICATION.

Sir,

I have read your Editorial of the 13th inst. with interest in regard to what transpired at the Midland Counties V.M.A. I feel sure that the points mentioned are not the real cause of many veterinary surgeons feeling aggrieved at the working of the Tuberculous Order. What I, and others to whom I have mentioned the matter, object to, is, that when you have reported, another V.S., often quite a young man, comes into your district, sometimes parading his authority and in other ways "showing off." I am not ashamed to say that I do strongly object to this for reasons any practitioner can understand. Is it fair that an outsider should come right among my clients, even to within a mile of my residence, to carry out the terms of this Order?

I do think every V.S. ought to have the inspection of a certain radius round his own district, which would save much friction and also unnecessary expense. Fancy sending a man about 18 miles to a farm which is within a mile of my house, to apply the tuberculin test!

Of course, sir, I know I am bound to report cases coming under my notice, and should never think of doing otherwise, but I do say it is placing one in an invidious position. I suggest that all veterinary surgeons not inspectors should memorialise the Board of Agriculture to represent to the various County Councils this *real grievance* under which the private practitioner at present is labouring. It is admitted that this Order is to be a great help to the veterinary profession, so why not have a more equitable arrangement which will allow wider distribution of the fruits? My candid opinion is that the practitioner who is not also a veterinary inspector is going to have to submit to many indignities, and have his practice much curtailed.

With your permission, sir, I should be glad to hear if these suggestions of mine are favourably received, when arrangements could be made to bring the matter before the proper authorities at an early date.—Faithfully yours,

C.

A CAUSE OF "EMACIATION."

Sir,

When the Tuberculosis Order came into force in May last, a deal of judgment was required to discriminate between poorness and emaciation. The former arising from the poor quality of the hay upon which the cattle were fed during the previous winter, and the latter being the result of disease, probably tuberculosis. I would now point out that another factor has arisen, which may make it difficult to arrive at a correct diagnosis. I allude to the presence of the *Distoma Hepaticum*, which as is well known to the older practitioner, causes extreme emaciation of the host. I came across a case under the Order yesterday, but fortunately for me the beast was affected with tuberculosis also.

—Yours faithfully,

Swindon. Sept. 17.

J. C. COLEMAN.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1316.

SEPTEMBER 27, 1913.

VOL. XXVI.

A POINT IN DIAGNOSIS.

In a clinical note this week, Mr. W. T. D. Broad calls attention to a diagnostic procedure which, so far at least as tuberculosis is concerned, is perhaps not sufficiently regarded in this country. There is, of course, nothing new in rectal exploration for the detection of tuberculous proliferations within the abdomen; but it is not very often heard of as a routine diagnostic measure. There are writers upon tuberculosis who, if they mention it at all, do so with a certain amount of reserve; and we fancy that few of our members have yet regularly practised it. It is recommended by so high a clinical authority as Ostertag; and Mr. Broad's experience supports the opinion of the great German expert.

SALVARSAN.

Recently there have been a number of reports from abroad upon the successful administration of salvarsan to animals. These may induce some English members to give the drug a trial—for there are animal diseases in this country for which salvarsan may well be worth a trial. But anyone making the attempt would do well to first consider the history of salvarsan in human medicine, and the present views regarding the administrative technique and contra-indications.

Our records of the action of salvarsan upon veterinary patients are few; and we may learn much from the incomparably richer experience of the medical profession. Salvarsan leapt into wide popularity in the treatment of syphilis; and for some little time—until a larger experience of it was available—its use was held by many to be practically devoid of danger. That view has since been modified; and the drug is now used with much more care and discrimination. This may be taken, not as a warning against the use of salvarsan, but to emphasise that it should be introduced into veterinary practice cautiously. Its value in human medicine is now beyond question; and it may prove to be equally valuable in some veterinary conditions.

AN INNOVATION.

At a recent meeting of a local Society, four of the members submitted microscopical specimens. Hitherto, with exceptions few and far between, microscopic demonstrations have been by teachers from one or other of the veterinary schools. The old-time "paper" at these meetings, often wearisome and unprofitable, is slowly giving place to shorter and more profitable "introductions" of the subjects, to "impromptu discussions," and to extended series of specimens with verbal clinical notes. Each of these changes should add something to the life and interest of the meetings, and just now the latest will not be the least appreciated.

"EPHEMERAL LAMENESS"—REMARKS.

By E. WALLIS HOARE, F.R.C.V.S.

The above is a "coined" term, to express a form of lameness which is of remarkably short duration and recovers spontaneously. Probably it is already familiar to many practitioners, but has not received any degree of attention. A consideration of the subject may not be pleasing to all minds, because one has to admit a certain amount of ignorance with reference to diagnosis; and moreover the cases I shall attempt to describe are not by any means "paying" ones. They recover so quickly that second visits are countermanded, and even the ubiquitous bottle of embrocation or "white oils" is not used up before the horse is again fit for work.

The lameness appears either when the horse is at work or in the stable. In a case met with lately, the horse was attached to a heavy van, and while at a walking pace, suddenly went so lame in the near hind limb that he had to be taken out of harness. On examination I found that no weight could be borne by the limb, and it looked like a case of fractured pelvis. But nothing abnormal could be detected in any part of the leg. A "wait and see" diagnosis was given, and the horse was with difficulty led to his stable: the onlookers remarking that "any d— fool could see that it was a 'broken leg.'"

Next morning I was surprised to find that the horse was working as usual, and not a trace of lameness was present!

What an opportunity for a lightning diagnosis and for a prognosis, likewise for a demonstration of the miraculous powers of "white oils." But alas! the risk was too great, and I have to be content with the thankless "wait and see" diagnosis.

In another case a horse was found by the stableman in the early morning, so lame that a broken leg was suspected. On attendance I found the animal very lame in the off hind, and on movement he placed but little weight on the limb. Progression seemed to cause pain. Nothing abnormal could be detected. As some diagnosis had to be given, the muscles of the hip seemed a safe region on which to expend the energies of the stableman with fomentations and liniment, until the visit on the following day. But *mirabile dictu*, an early telephone message came on the following morning, that "Persimmon" was quite sound and would be put to work. This news was not altogether pleasing, because the owner did not belong to Sam

Weller's "advice free" order, and visions of a good space in the ledger were shattered.

I could recall several other cases of a similar kind in the hind limb, but wish to draw attention to the fact that cases may also occur in a fore limb. These I have observed especially in fresh horses, and those having high action. The lameness may occur either in harness or in the saddle. The attendant in one instance stated that when driving quickly in the street, the horse suddenly went "dog" lame. In another case the horse was being ridden, and quite close to his stable he went so lame that he could only be with difficulty brought home.

At first sight the lameness simulates "dropped elbow," and, indeed, in one instance I diagnosed it as such. But on the following morning I was reminded of the veracity of the hippocratic aphorism, "Experience is fallacious and judgment difficult," because the horse was going quite sound.

What is the nature of these cases? I candidly admit that I do not know. Probably if I possessed the skill of the well-known Professor, who, from hearing the sound of a horse walking, could distinguish the lame leg and recognise the seat of the lameness at a glance. I might be able to venture an opinion, but I am reminded that the Professor was most careful to examine the foot in every case, so after all his skill was not beyond that of ordinary mortals.

The diagnosis of lameness will always prove to be one of the most difficult problems in professional work, and the prognosis is certain to cause much "stretching of the pia mater." Progress in both these directions has been slow, and in many instances is more apparent than real. Dogmatism still succeeds in gaining reputations, and the assumption of super-natural skill proves a valuable asset to the tactful practitioner. He may endeavour to persuade his professional brethren that his skill is founded on a profound knowledge of anatomy and physiology, but those who are "in the know" are well aware that the sciences named have been for many years "closed books" to him.

Cleverness has been defined as "Knowing your own ignorance and being able to conceal it from others;" and few will deny that, in the diagnosis of lameness, this type of cleverness is a very essential element to those who seek to obtain and maintain a reputation that is "oft won without merit."

The diagnosis of lameness offers a grand and unlimited scope for dogmatism and bluff, because the correctness of the opinions given can but seldom be tested by post-mortem examinations. So the consultant, Sir Oracle, or Professor Gamaliel, is able with impunity to differ in opinion with the ordinary practitioner, and to make him feel small. If the case has been treated for hip lameness, the consultant instantly jumps to the hock, and if the case recovers he gets the credit. But if the truth were known, the consultant is quite as much in doubt as the attending V.S., yet the fact remains that by treating the hock, so much time is occupied that, in the event of the cause of lameness being anywhere else, if curable, the case recovers by means of that very useful therapeutical agent—*rest*.

Some are able to "go one better" and treat two regions simultaneously, with the plausible excuse that by blistering one joint the movement in the other is restricted. Or, if in a doubtful case the attending V.S. abstains from giving a definite opinion, the consultant with the utmost *sang froid*, declares the existence of a fracture, but, mark you, always a *curable* one, thus adding to his false reputation, when the case recovers by the *vis medicatrix naturæ*. Protected by the fact that post-mortem examinations are not likely to be held on such cases, the opinions given are sometimes grotesque in the extreme. The wonder is how the owners of the horses manage to swallow some of the fairy tales that are manufactured by the "successful and practical men."

On calmly considering the matter one is led to enquire how many diagnoses of lameness are correct. No doubt when pus is found in the foot the veriest neophyte can boast of his diagnostic powers, but the finding is very often a difficult procedure, and is not accomplished by the observation of peculiarities of action. Even the greatest "specialist" in lameness would hesitate to give a definite opinion until he had made a careful examination of the foot, thus showing that in this respect at least he has not advanced from the knowledge possessed by his ancestors. But in cases where nothing is found in the foot, and the horse either recovers or remains lame for an indefinite period, who can say as to the actual seat of the lameness. The old rule for a "working" diagnosis still remains good—if in doubt *re* the fore leg, say the lameness is in the foot; if in the hind limb, say it is in the hock. To this one might add that the term "rheumatism" is a very convenient one in practice—it will cover a multitude of blunders.

Avoid the term "navicular disease," it is a difficult hole to get out of, and clients know too much about its progressive nature and incurability. But rheumatism of the sensitive laminae or of the navicular bursa, is a useful term, because rheumatism is a "peripatetic" disease, and enables us to alter our diagnosis without confessing our error. And after all, why should not rheumatism affect the structures named and account for those obscure forms of foot lameness which time proves are not due to navicular disease. Besides, one has always the crutch to lean on that the rheumatic cases *may* develop into navicular disease, so we can adopt a "wait and see" diagnosis.

Ditto, ditto, as regards hock lameness; incipient spavin, or rheumatism of the hock, is a useful term, and peradventure if the case recovers, but no spavin appears, we can still wriggle out of the difficulty for, as already remarked, by treating the hock, time will be given for the real cause of the lameness to disappear, but the converse does not hold good. At any rate, the hock is a safe location for the majority of cases of hind leg lameness.

The Irish returns this week show only seven cases of sheep-scab. Under all other headings of diseases there is a blank.

DIAGNOSIS OF TUBERCULOSIS.

Subject.—A five-year-old roan shorthorn cow, which slipped calf two or three months ago, and turned out as a barren. She had not thrived since aborting, but the last month had fallen away rapidly. Auscultation revealed slight abnormal respiratory sounds and pericarditis with fluid in the pericardium.

This brought to my mind wire, or some other sharp foreign body, having pierced its way from the stomach. As a result of my earlier cases under the Tuberculosis Order, I found I could frequently palpate some of the grapes lying on the rumen by rectal examination. I accordingly examined her in this manner, when I found a large number of what felt like peas under the hand on the rumen.

I had her slaughtered, along with another, without further test. Post-mortem revealed the inside of the pericardium, which contained a lot of fluid, and the epicardium literally studded with tubercles; two or three egg-sized caseous masses in each lung, and two large mediastinal glands. The peritoneum, liver, and other abdominal organs were thickly studded with tubercles from the size of a pea to a bean.

There was no turning out of the elbows, or œdema under the chest, or dewlap during life.

WM. T. D. BROAD, M.R.C.V.S.

Marlborough.

ABSTRACTS FROM FOREIGN JOURNALS.

THE USE OF PITUITARY EXTRACT IN BOVINE AND EQUINE OBSTETRICS.

The power of stimulating uterine contraction in the human being and in the small domestic animals which is possessed by extracts of the infundibular portion of the pituitary gland, is now well known. Hans Schmidt and Michael Kopp, two veterinary surgeons of Wolfratshausen, have been trying the agent this year, as occasion offered, in bovine and equine obstetric practice. They have used a 15 per cent. infundibular extract, which is supplied by the "Chemischen Fabrik" of Aubing, in 10 c.c. ampullæ, and with this they have treated six cases. Four were treated by the two men conjointly, and two by Kopp alone, and all are now reported at considerable length. The following is a very brief *resumé* of each.

The first case was a cow at her third parturition. A living calf was born, and the after-birth was discharged naturally after a few days. Nine days after calving the authors found her suffering from purulent metritis. The uterus was greatly enlarged and contained great quantities of pus, a portion of which was removed by massage of the organ through the rectum. The uterine walls were completely flaccid, and did not contract upon syringe out with hot solutions, which had to be drawn away with the uterine catheter. The next day no

uterine contraction had taken place, and 10 c.c. of pituitary extract was injected. This was followed after five minutes by powerful expulsive efforts, which lasted for about ten minutes and were accompanied by a copious discharge of pus. Rectal exploration then showed the uterus to be well contracted and sharply defined. The case did well.

The second case was a heifer, 2½ years old, a primipara. For two days she had shown violent labour pains without delivery. Kopp, examining her on the third day, found that the pains had quite ceased. He diagnosed a complete torsion of the uterus, and after rectifying this by rolling the heifer, he ascertained by vaginal and rectal exploration that the os uteri was closed, and that the calf was dead. The injection of 10 c.c. of pituitary extract was followed in a few minutes by the onset of violent labour pains, which were maintained throughout the parturition. The os uteri opened naturally, the calf was extracted with manual assistance, and the case did well.

The third case was a cow, the number of whose parturitions was unknown. For a space of five days she showed frequent straining, with appearances resembling labour pains. Kopp examined her three days after the expiration of this period. He found the os uteri partially open, permitting the passage of a finger. The calf was dead, and there was a foul-smelling discharge in the vagina. The temperature was 104.3 F., and no labour pains or straining were present. A first injection of 10 c.c. of pituitary extract had no effect, and the same dose was therefore repeated fifteen minutes later. This was followed by slight appearances of labour pains, and the dilatation of the os uteri till it permitted the passage of the hand. It was then possible to extract the foetus and disinfect the uterus, and after this had been accomplished the case did well.

The fourth case was a mare ten years old, at her second parturition. This animal had shown labour pains since the day before, and appeared completely exhausted when examined. The vagina was narrow, and the os uteri was only partially open, closely surrounding one foot of the foal. One injection of 10 c.c. of pituitary extract had no effect beyond inducing some attempts at straining, so the dose was repeated ten minutes later. This was followed by the onset of powerful labour pains, and by the dilatation of the os uteri in about ten minutes. After ten minutes more the foal was born without special assistance, and the case did well.

The fifth case was a newly-purchased heifer, 2½ years old, a primipara. This case was seriously complicated by fatigue arising from transport, and by cardiac weakness. Violent labour pains had appeared early in the day and had ceased towards the afternoon, and the animal, when examined by the authors in the evening, was unable to stand. The os uteri was closed. In this case three injections, each of 10 c.c. of pituitary extract, were given at intervals of half-an-hour, the authors thinking it advisable to push the drug on account of the exhausted condition of the heifer.

The first dose was quickly followed by a return of labour pains, and the second by opening of the os uteri and protrusion of the membranes. The third caused violent pains (throughout which the heifer was still unable to rise), and the birth of a living calf ensued without assistance. No untoward results followed the three injections.

The sixth case was also a heifer 2½ years old, and a primipara. In some respects this case greatly resembled the last one, as it was complicated by extreme exhaustion from transport. There was, however, no special cardiac weakness; but there was the additional complication of a torsion of the uterus. When this was recognised, the animal was unable to stand; and, after it had been rectified by rolling, even the application of an electric current failed to induce her to rise. The os uteri was closed. In this case, also, three injections of pituitary extract were given, causing the speedy appearance and gradual increase of labour pains. The os uteri opened and dilated by degrees; and, despite the exhausted condition of the heifer, a living calf was extracted.

In all these serious cases, the pituitary extract quickly induced vigorous contraction of the uterus; and in no case was this accompanied by tetany or any other undesirable effect. The authors therefore regard the agent as a valuable addition to veterinary therapeutics.—(*Münchener Tier. Woch.*)

THE LIFE-HISTORY OF *SCLEROSTOMUM BIDENTATUM*.

Reinhold Stier reports (*Archiv. f. Wissenschaftl. und prakt. Tierheilkunde*) the results of investigations upon this subject which he has carried out in Prof. Schütz's Institute. His conclusions are summarised as follows;—

1. Almost every horse is affected by one or several aneurisms of the ileo-cæco colic arteries and their branches.

2. The average internal length is 2¾ to 2½ ins., the internal circumference 2 inches, and the average thickness of the wall 1-6th to 1-5th inch.

3. One or several thrombi with parasites are always found in the aneurisms in winter, and not rarely in summer.

4. The number of parasites is smaller in summer than in winter.

5. The worms found in the vessels are always young forms of *Sclerostomum bidentatum*.

6. The most abundant intestinal nodules and the majority of sexually mature parasites are found in the cæcum. *Sclerostomum edentatum* is more frequently found in the intestine than *Sclerostomum bidentatum*, and the latter is far commoner than *Sclerostomum quadridentatum*.

7. The author has not found young forms of *Sclerostomum bidentatum* in the intestine and its membranes.

8. On that account, and for several other reasons, the author concludes that the parasite develops up to a certain stage in the mesenteric artery, and only reaches the intestinal wall by way of the blood-stream about the period of sexual maturity.—(*Münchener Tier. Woch.*)

TEMPORARY BLINDNESS.

Lechle, of Aub, reports the following peculiar case. A horse during the period of warranty was objected to on account of chronic diarrhœa. He was then placed in the stable of a referee, and, while there, showed a violent attack of delirium, with subsequent unconsciousness. This had passed off when Lechle first examined him.

In the next few days Lechle examined the animal with regard to staggers, and found that complete blindness was present. The horse ran against obstacles in his path, but was responsive to the voice and touch of his driver. Nothing abnormal could be seen by an examination of the eyes, beyond the complete blindness.

Four or five days later, Lechle again examined the animal, and found to his astonishment that the vision was completely restored.

A peculiar feature of the case was that the horse, which had previously been suffering from diarrhœa, showed temporary constipation both shortly before the attack of delirium, and also before the ephemeral blindness. Lechle suggests the possibility that alteration of the blood pressure in the brain had set in as a consequence of that in the intestine, and had caused the attack of delirium and the paralysis of the optic nerve. No recurrence of these attacks took place, but the horse was soon sold elsewhere, and Lechle therefore lost sight of the case.—*Münchener Tier. Woch.*

A PROTRACTED CASE OF TETANUS.

Solleder, of Lauingen, reports the following case, which is noteworthy on account of its unusually long duration. A young horse, a yearling, was operated upon for umbilical hernia, wooden clamps being used. The clamps fell off 15 days later, and the wound healed very well. Five weeks after the operation, Solleder was again called to the animal, and found it suffering from tetanus. Infection appeared to have occurred through a small moist place upon the old wound.

The most different methods of treatment were adopted, but the animal's condition remained unchanged for a period of *fourteen weeks*. The symptoms present throughout that time were mild trismus (the animal took food well), marked projection of the membrana nictitans, stiffness of the neck with violent contraction of the cervical muscles, and groaning at every exertion. Improvement began to appear after the time mentioned, and the animal lay down for the first time more than three and a half months after the beginning of the illness. After another four weeks the last symptoms of illness had disappeared.—*Münchener Tier. Woch.*

ATRESIA VAGINÆ HYMENALIS.

Schenkl, of Geiselhöring, records the case of a four-year-old mare, supposed by her owner to be suffering from a prolapse of the vagina. Upon examination Schenkl found a red, soft, bladder-like swelling between the lips of the vulva. Schenkl attempted to explore the vagina, and found that this abnormal swelling prevented access to it.

Schenkl threw the mare, and incised the bladder-like formation, the result being the escape of clear glassy mucus. It was now possible to reach the os uteri through the opening made by the incision. The case was, therefore, only an apparent prolapse, being really a closure of the vagina. The secretion which had collected behind the occluding wall had caused the latter to bulge outwards after the manner of a prolapse.

A portion of the occluding membrane, about the size of the palm of the hand, was removed, the bleeding was arrested by compressing the lips of the vulva together, and the mare was then allowed to rise. The treatment was completely successful. —*Munchener Tier. Woch.*

W. R. C.

SOUTH DURHAM AND NORTH YORKSHIRE VETERINARY MEDICAL ASSOCIATION.

The annual meeting and dinner was held in the Imperial Hotel, Darlington, on Friday, Sept. 5th. The retiring President, Mr. W. Awde, Stockton-on-Tees, was in the chair. There were also present: Messrs. G. R. Dudgeon and T. T. Jack, Sunderland; T. Wilkinson, Lanchester; J. Wilson, Yarm; P. Snaith, Bishop Auckland; H. Peele, Durham; P. B. Riley, Barnard Castle; W. N. Dobbing, C. G. Hill, F. H. Sanderson, and J. H. Taylor, Darlington.

Mr. HILL proposed, seconded by Mr. Dudgeon, and carried, that the minutes of the previous meeting as they had appeared in *The Veterinary Record* be taken as read and confirmed.

The President-elect, Mr. J. M. Walker, wired that he much regretted being unable to be present, and Messrs. Morton, Forbes, and Blackburn wrote that they had engagements which prevented them attending.

Messrs. T. WILKINSON, Lanchester; and T. T. JACK, Sunderland, were unanimously elected members of the Association on the proposition of Mr. Dudgeon, seconded by Mr. Hill.

CLINICAL CASES.

The HON. SEC. said that he had recently been called in to make a post-mortem on a foal. The foal had been out at grass with its dam about a mile from the owner's house, and was seen once a day by the groom, about five o'clock in the evening, when they were fed. Both mare and foal were all right when seen on the Saturday evening, but on going to see them the next evening the foal was dead. The foal was removed to the kennels. On removing the skin, there was a bruise on the left flank about the size of the palm of one's hand, the subcutaneous tissue being much infiltrated with serosity. On opening the abdomen a quantity of faeces and fluid escaped, and on carefully examining the bowels a rupture about three inches long was found in the small bowel, around which, in the peritoneal coat and mesentery, was extravasated blood. He came to the conclusion that the mare had most probably kicked the foal in the flank, and the bruise and rupture had resulted. The owner had seen the mare kick the foal on more than one occasion when he went too roughly for his milk.

HEAT TROUBLE IN COWS.

Mr. HILL asked if any of the members had had any of these cases lately, as he had been called to several. All the cows showed nerve trouble, would walk a short distance and fall down, and he had three such cases in one week. He found that when they were placed in a

dark box and kept quiet for a day or two, they soon recovered.

FEES PAYABLE TO VETERINARY INSPECTORS BY THE NORTH RIDING COUNTY COUNCIL.

The SECRETARY said that he had written to the Clerk of the North Riding County Council, according to the instructions which he received at the last meeting, and had asked the Clerk to bring the fees which the inspectors would like altering, before the Executive Committee at their next meeting. The Clerk had replied that he would do as he was requested.

Since then, however, Mr. Pratt, Chief Veterinary Inspector for the North Riding County Council, had been to see him (the Secretary) and talked the matter over with him, and had pointed out that, in his opinion, it would be better to leave some of the fees as they were, as if altered it would be to the disadvantage of those inspectors who had long distances to go, in which case they were paid better, when paid by the hour, than if they received a fixed fee as in Durham.

Mr. AWDE thought that as there were so few North Riding inspectors present it would be better to defer the matter.

Mr. DUDGEON said that they in Durham were generally satisfied with the fees they now got, which were a great deal better than formerly, and he thought that this matter was one which concerned the North Riding inspectors, and that they should take the matter up.

Mr. HILL suggested taking a referendum on the points which they desired altering.

The SECRETARY said that he hardly thought the inspectors would take the trouble to reply. And in support of that he might say that when he called a special meeting of inspectors of the North Riding to confer with the inspectors of Durham County Council, only two, out of a possible sixteen, outside their Association, came to the meeting, the remainder ignoring the matter completely.

Mr. HILL suggested that perhaps if they called a meeting at some other place more might attend, and it was then generally agreed that a meeting be held at Northallerton on an early date, to which all North Riding inspectors be invited.

FINANCIAL.

The TREASURER presented the annual financial statement, which showed that the Association had a balance in hand of £10 6s. 10d. He said that he should like to thank the members for paying their subscriptions so promptly, as he was thus enabled to say that there was not a single outstanding subscription.

It was proposed by Mr. Snaith, seconded by Mr. Dudgeon, and carried, that the balance sheet be adopted and the accounts paid.

As the President-elect was not present the reading of his presidential address was deferred until the next meeting.

FOOT-AND-MOUTH DISEASE.

By W. AWDE, F.R.C.V.S., Stockton-on-Tees.

Foot-and-mouth disease — Aphthous Fever — is an acutely infectious disease which chiefly attacks ruminating animals, and pigs. It is also said to infect horses, dogs, and cats, and even poultry, but such cases are extremely rare, and have probably never occurred in this country. Cattle, pigs, and sheep, are the animals which are most affected by it.

Symptoms. From three to six days, as a rule, elapse from the time of infection (but in some cases from two to ten days, and in the case of the pig only one day) before the animal sickens. It is a sort of exanthematous fever akin to small-pox, measles, scarlet fever, and the like—that is to say, the disease begins with an ache

throughout the system, and a fever, which, after one to two days, is followed by an eruption. When this has come to a head the fever almost or entirely ceases.

The first symptoms, therefore, are that the animal seems unwell, eats less, and, if it is a milch cow, gives less milk. The temperature rises at once, but this fever only lasts a couple of days, and in slight attacks it may be quite low. Vesicles or bladders begin to form in the mouth, and occasionally on the lips, snout and nostrils, on the skin round the hoofs—in cattle mostly in the cleft between the hoofs—and in pigs mostly immediately above the hoof on the outside, and in the skin of the foot joint. In many cases the skin round the teats is also attacked and occasionally eruptions occur in the vagina in female animals.

The eruption consists in the formation of surface vesicles, the epidermis or the epithelium of the mucous membrane being lifted up in many places by an exuded watery liquid. The vesicles are small at the start, but usually increase quickly in size; this is especially the case in cattle and this fact seems to have some connection with the fact that the epidermis of these animals is very thick, especially between the hoofs and on the tongue, so that it offers greater resistance against the exudation pressure. The acute exudation, of course, causes pain, with the result that the animal goes lame, limps badly on the affected limbs, shakes its feet, lies down a great deal, and is unwilling to rise. Sheep and pigs sometimes creep about on their knees. Cows seem afraid to eat, keep the mouth shut, and make a loud smacking noise with their lips. Saliva forms in the mouth and dribbles out in strings. If the cow's mouth is opened—a process which she is apt to resist—the characteristic vesicles will be seen. They occur mostly on the surface of the tongue, especially on the flat part in front, but also on the thick part farthest back. The number of bladders or vesicles is not large, as a rule, often only five to six, but frequently they increase quickly in size. They are usually the size of a shilling to half-a-crown, and sometimes attain a couple of inches in diameter. Large vesicles are likewise often to be found in the fore part of the toothless gums of the upper jaw, and smaller ones on the inside of the lips, on the palate and cheeks, and less often on the underside of the tongue. As the epithelium on the back of the tongue is very thick it cannot be determined at first whether it really is a case of vesicles, but the eruption takes the form of large flat lumps covered by an apparently normal epithelium. If one tears a hole in one of these lumps, a clear liquid comes out. The epidermis can be loosened for some distance (sometimes one can tear away a piece of "skin" a couple of inches in diameter from the front part of the tongue) revealing a red—often very red—sore which is very apt to bleed. This exposure of the naked mucous membrane causes the animal sharp pain, which it shows by shaking its head violently, and at times it is driven quite wild. A little later the bladders burst by themselves without any such interference, and the loosened epithelium is detached, leaving large red sores. Often, however, the epithelium remains hanging on to either side of the sore, and, in its macerated whitish state, is then apt to present some resemblance to a loose croupous deposit.

Approximately the same process takes place in the cleft between the hoofs. Here the bladders or vesicles mostly begin at the back, but, as a rule, they combine into one immense bladder, which extends throughout the length of the cleft, and after it has burst and shed the whitish-yellow "boiled" looking epidermis, a large red sore is exposed.

On the teats the vesicles may at first be very small but numerous. Often there is an annular vesicle round the mouth of the teat itself. The eruptions when occurring on the teats often combine into large flat, somewhat

flabby, irregular vesicles of a whitish-yellow colour. These are easily torn in milking, and the epidermis soon cracks, as it is very thin at this point. The bladders are here also succeeded by reddish surface sores, which take some time to heal on account of the milking.

In other respects it may be said to be characteristic of the disease that it is very superficial. It amounts to a simple raising of the epidermis or epithelium of the mucous membrane caused by a serous exudation. There is no deeply-rooted inflammation of the mucous membrane or corium; the sore simply consists in the laying bare of the surface of these parts, and it has a natural tendency to heal quickly. In a case of a deep sore which destroys the corium or mucous membrane itself, the healing may be effected by the sore being filled with granulations, and the final healing may take place very slowly through the epidermis, gradually stretching out from the sides; but in foot-and-mouth disease there are always small patches of cellular tissue at the base of the sore, down between the papillae of the mucous membrane, and the sore may therefore in a very short time be covered with newly formed epidermis over the whole surface simultaneously. Thus it is found that these large sores can heal in eight days or less. The locality of the sore may, however, be traced for some time by a smooth, slightly depressed, thin-skinned patch, as, of course, some time elapses before the epidermis reaches its normal state.

Owing to secondary infection of the sore more severe inflammation may, of course, arise later on, but this occurs extremely seldom in the mouth, especially when the animal is given suitable, soft and clean fodder. It is more apt to happen when the disease attacks the feet, especially the hind legs, and when the animal stands in manure or dirt mixed with urine, as, for instance, in dirty stalls without litter.

Under such conditions deep gangrenous inflammation of the skin between the hoofs, sometimes even involving the tendons and joints, is frequently met with, and is due to infection with the necrosis bacillus which occurs so largely in manure. Other bacteria can, of course, also enter the sore and give rise to inflammatory processes. The teat sores may, as above stated, become irritated by the milking, and they are also liable to be infected when the animal's litter is dirty, and deeper sores may thus be formed, which will heal slowly. What is more dangerous still, bacteria may penetrate from the sores which frequently form on the tips of the teats into the lactiferous ducts and cause inflammation of the udder, which often leads to the destruction of one or more quarters. Apart from these complications which, under favourable conditions, and when the animal is well looked after, are not very frequent, the disease is usually not a dangerous one. The cow attacked by it is usually very ill for some days, eats little or nothing, gives little milk, which, however, contains more fat than under normal conditions, and becomes very emaciated; but about three to four days after the mouth complaint has begun she begins to eat well again, she grows fatter, and resumes giving a satisfactory amount of milk. The foot lesions often cause inconvenience a little while longer, but given favourable conditions these also heal surprisingly quickly, and most animals seem quite well again after one or two weeks.

Sheep and pigs usually have less violent attacks than cattle, and they are more liable to the foot disease than to the mouth disease, which often escapes notice. Pigs, however, often shed the entire horn of one or more hoofs, especially when affected animals are forced to walk.

In these circumstances is it not a very mild disease, which it is hardly worth while making such a fuss about? This was the general opinion in the old days. It was not until 1878 that the disease was scheduled as a contagious disease, for which the law required that infected cases should be rigorously isolated. Before

that time the public authorities usually did very little to prevent the spread of infection, and as a result the disease spread all over the country and was particularly prevalent about forty years ago. At that time I remember seeing any amount of animals affected with the disease, and they generally made good recoveries, although in the case of milk cows they usually lost flesh and the secretion of milk was arrested for some time.

It is quite natural that many a farmer whose stock has had the disease in a mild form thinks that the isolation is worse than the disease itself, but it is, nevertheless, with good reason that public opinion has undergone such a change during the last thirty to forty years. As a result it is now regarded as one of the most harmful diseases amongst domestic animals, and the greatest efforts are now being made to keep it in check whenever it makes its appearance. Although the disease is rarely fatal, it is acutely infectious, which makes it serious. When it is left alone it spreads to an enormous number of farms, and with the present quick and easy means of communication it might quite easily extend to nearly all the farms in a county if repressive measures were not adopted.

The great loss in connection with the disease is first due to the decreased secretion of milk. During the illness itself the yield of milk is nearly always greatly reduced, often to half the normal or less. However, as soon as the animal begins to eat again, it usually rises, but it is only in exceptional cases, after very light attacks, that the secretion of milk again comes up to the normal. Moreover, it is not unusual for a cow, when attacked by the disease whilst dry, to yield very little or no milk after calving, in spite of the fact that the udder is to all appearances healthy. The same may apply to cows calving whilst in the grip of the disease. In nearly all outbreaks some cows contract inflammation of the udder, with the result that many become more or less worthless for milking, whilst some cows get a malignant and persistent hoof complaint which weakens them greatly. A number of young calves and pigs die, as well as adult animals occasionally; abortion is also liable to occur; tuberculosis may sometimes suddenly attack a herd after it has been through foot-and-mouth, and, of course, the emaciation caused by the disease is a matter of great importance when dealing with cattle fattened for killing. In Germany the loss is put down at £2 10s., and in Holland at £2 per cow. To this must be added the fairly heavy expenses which are required for the proper care of the sick animals, and the difficulties in connection with trading.

OUTBREAK IN NORTHUMBERLAND, ETC.

To come nearer home to the recent outbreak of the disease in this county and the adjoining northern counties, as you know the disease was introduced from Ireland in cattle brought over from that country by boat, and the disease was not detected until after the animals forming part of the cargo were landed, and in some cases sold by the Irish dealers on to English farms. As many farmers depend entirely on Ireland to send them store cattle for grazing and feeding purposes, these animals were sent all over the country, with the result that foot-and-mouth disease appeared in several places at the same time. There is no doubt at all that the Irish dealers knew the animals had the disease when it first began to show itself after their arrival, and they did their best to get rid of them at some price or other, and succeeded only too effectively.

In one case which came to my knowledge, Webb, of Carlisle, sent a telegram to a farmer close to Alnwick telling him that he was sending him some cattle on by train, a thing he had never done before. Fortunately the farmer was a cautious man, and before their arrival he removed the stock all round the field where he proposed to put them, so that, although the cattle arrived

suffering from foot-and-mouth disease, or developed it very soon afterwards, as soon as the infected cattle were slaughtered out, there was little or no risk to his adjoining cattle, or to the stock belonging to neighbouring farmers.

The symptoms of the disease in Northumberland were not so well marked or so virulent as in some previous outbreaks, but as the animals were at grass keep, this might account for some of the slight differences observed. For instance, it was quite exceptional to hear a cow smack her lips, whereas previously, this was noticed in nearly all the cases seen. In some animals only mouth lesions were observed, and little or no lameness, whilst in others well marked foot-and-mouth lesions were found. I have seen a beast chewing its cud, and while it did so, observed that there was a sore on the tip of the tongue, and one three inches higher up left after rupture of foot-and-mouth vesicles had taken place; diagnosis in that case being a very easy matter indeed. In this country it is the custom to slaughter all affected animals and those immediately in contact, it may therefore be useful to give you an account of the procedure adopted by the Board of Agriculture in dealing with such outbreaks. Whenever a case of foot-and-mouth disease is reported to the Board, either by a local or a county veterinary inspector or by the owner, the Board immediately send one of their veterinary staff to see the animals and examine them. If after his examination he is satisfied that the diagnosis is correct, he then wires to the Board confirming the existence of the disease. On receipt of his report the local police are straightaway posted outside the field where the disease exists, and as soon as possible a valuer is engaged to value the animals it is proposed to take for the Board. The owner can also have his own valuer if he likes, but in every case has to agree to the valuation made, and to sign it before the slaughter is commenced. When farm buildings can be made use of for slaughter it is generally undertaken in them. In many instances, however, these could not be utilised on account of the distance between the fields and the buildings necessitating cattle being driven over roads, etc., and the operation had to be undertaken in the open fields, hangers being erected to dress the carcasses on, after which they were floated into barns or open sheds to hang till they were set and could be removed by motor lorries to town for food. These operations were undertaken by the lay staff, and the digging of cremation pits close by for burning the offal. In the case of affected animals where the carcasses cannot be utilised for food, they are cremated altogether, but otherwise only the heads and feet, viscera, etc., are burnt.

The veterinary staff superintend the examination of the carcasses, and say what carcasses are fit for human food, etc. They also examine all cattle in close proximity to the infected place daily for at least a fortnight, and then subsequently for another fortnight or so, every other day, and during the latter period extend the area so as to include all the stock within a very large area outside the infected place. Of course restrictions are placed on the movement of animals either into, or out of, the district outside an infected place in the first instance, and nothing is allowed to be driven either on or across a road. Animals fit for food are slaughtered in the fields where they are grazing, and the carcasses carted to the slaughterhouse. Movement of animals generally is prohibited, and any required movement of any kind can only be sanctioned by granting a license, and usually for slaughter only within four days. All persons going on to infected premises are warned, and are not allowed to leave without having their boots dipped into disinfectants. All those going on to the place where the disease has been, before the places have been disinfected, have to wear overall clothing, which must be left behind them, and either destroyed or dis-

infected before removal from the premises. All hides are soaked in disinfectants before being taken away. The fields themselves are quicklimed where there has been traffic, particularly about the pens and gateways where the slaughter has taken place. All trees and hedgerows up to a certain height, railings, posts, gates, and other woodwork are quicklimed or whitewashed with lime; the droppings, too, are covered with lime. After this has been done the fields are left without stock for some weeks. All dogs on infected farms are kept shut up while there is any risk.

How is the disease spread? As the disease has broken out several times of late years in this country, and the seat of origin could not be definitely stated, we are entitled to ask this question, and think that the answer might supply a useful discussion. The disease has generally occurred near the coast, notably at Yarmouth, and in Kent, etc.

In many of these outbreaks it has not been possible to trace the source of infection, although birds, such as rooks, gulls, etc., have been blamed for carrying it either on their feet or through the intestinal tract after scavenging. Other animals such as foxes, hares, and rabbits have also been suspected of carrying the contagion from one place to another by their feet. The greatest danger of all, in my opinion, is from the saliva and ruptured vesicles.

Since this was written I have noticed in the newspapers that foot-and-mouth has broken out at Ashford, in Kent, and at Birkenhead.

Mr. SNAITH said that he would like to thank Mr. Awde for his exhaustive and interesting paper. He would like to know if human beings ever took the disease, for he thought he had seen it stated that they did contract it.

Mr. DUDGEON complimented Mr. Awde on his paper and said that he was probably one of the few who had seen foot-and-mouth disease when it was very common indeed, and when there were no laws to suppress it. He well remembered as a lad when walking down the streets of Sunderland with his father that he pointed out to him on many occasions tongues of beasts exposed for sale which had suffered from the disease. As time went on the disease was taken in hand by the Privy Council and he remembered on one occasion when assistant-inspector at the Port of Sunderland examining a cargo of sheep which had arrived from Germany. One animal was found to be affected, and this he marked privately, and put on one side, and detained the whole cargo. He was of course threatened to all sorts of penalties by the owners, and the next day his marked sheep had disappeared. However, three days afterwards when the inspector from the Privy Council came down, there were quite one hundred affected, and therefore his action was fully justified. There was no difficulty in those days in finding typical lesions of the disease. After an animal had been affected with the disease it usually thrived better, and cattle dealers would tell buyers at the markets that this or that beast had had the disease, and they could get a better price for them.

Mr. PEELE said he was sorry that on account of being late he had not heard all Mr. Awde had said. He remembered when at College seeing the disease for the first time, for the Principal, then the late Sir G. T. Brown brought many post-mortem specimens from Deptford for the students to see. He was then in Class A, but he took care to attend all the lectures upon it, and was always glad that he had done so. He was engaged during the outbreak of the disease last year in Northumberland, and from what he saw of it then, he was inclined to think that the disease was only of a mild character, and probably that was the reason why the disease had been overlooked when it was in

Ireland. The lesions he saw were only slight, and the salivation and smacking of the lips not present so far as he saw.

Mr. DUDGEON quite agreed that the last outbreak was only a mild one, and in many cases the tongue lesions were not well marked. He remembered years ago in one case when in taking hold of the tongue to examine it, the whole of the epithelium covering came off in his hand.

Mr. Awde was heartily thanked for his paper, on the proposition of Mr. Hill, seconded by Mr. Dugeon, and in replying said that he believed human beings could take the disease by drinking milk from an affected animal, and when so affected had soreness of the mouth. If he remembered rightly an inspector in Ireland took the disease and was affected in this way. He was glad that the members had enjoyed his paper. It ought to have been given last year, soon after the outbreak in Northumberland, but time had been taken up at the meetings with other matters, and the paper deferred. One did not often come across the disease, but it was always well to be fully prepared with the symptoms in case one did.

The members subsequently had dinner together, and afterwards a musical entertainment was enjoyed, many taking part, and as time went on, much latent talent was developed.

JAMES H. TAYLOR, Hon. Sec.

SOUTH EASTERN VETERINARY ASSOCIATION.

A meeting was held at the Saracen's Head Hotel, Ashford, on Wednesday, September 10th, Mr. E. Lyne Dixson, M.R.C.V.S., Margate, presiding in the unavoidable absence of the President. Among the members present were Messrs. T. A. Huband, Sevenoaks; J. H. Ripley, Hurst Green; W. W. Gulleford, Lympne; J. M. Richardson, Deal; Robert Elliott, Cranbrook; T. Hibbard, Gillingham; G. W. Dunkin, Canterbury; W. B. Edwards, Canterbury; J. Basil Buxton, London; W. R. Emery, Guildford; G. Fordham, Ashford; J. B. Dier, East Grinstead; P. J. Austin, Pembury; Elmer Ebbetts, Rochester; H. P. Hogben, Folkestone; T. F. Hogben, Ash; C. Crowhurst, Maidstone; Percy Gregory, Tonbridge; W. H. Crowhurst, Canterbury; F. C. Gillard, F. C. Golden Folkestone; Gerald Wachter, Ashford; and Theo. C. Toope, Hon. Sec., Dover.

The minutes of the previous meeting were taken as read and confirmed.

The HON. SEC. said he was pleased to report that they had five names to add to their number. He believed when they had elected the five new members they would number 54. Mr. Toope then proposed the election of Messrs. A. L. Wilson, London; Robt. Elliott, Cranbrook; J. H. Ripley, Hurst Green; J. Washford, New Romney; and C. W. Howard, Dorking.

Mr. CROWHURST seconded, and the proposition was carried unanimously.

The CHAIRMAN said before they commenced the business of the meeting he had a very painful duty to perform. That was to propose a vote of condolence with their respected President, Mr. James Crowhurst. He was sure he was only voicing the opinion of that meeting when he said they all felt most deeply for Mr. Crowhurst in the loss he had sustained by the death of his wife, who took such a great interest in the doings of that Association. He therefore proposed that a letter of sympathy be sent to Mr. Crowhurst and his family in their bereavement. The Secretary had handed him a letter from Mr. Crowhurst, who wrote from Leamington:—

"To the Members of the South Eastern V.A.

Gentlemen,—I am exceedingly sorry to feel unable to meet you so soon after the loss of my dear wife. I feel the ordeal of receiving the expression of your sympathy would be greater than I could bear. I am, therefore presuming on your kindness, and ask you to excuse my absence. I sincerely trust you will have a good meeting and one full of interest.

May I remind you that the work taken up at our first meeting has not yet been carried to a successful issue. I allude particularly to the improvement of the fees offered by the Insurance Companies. There has been much improvement in the fees allowed by County Councils, and there might have been still more but for the carping of some pessimists. I am of opinion that we ought to persist in advocating the restricted use of tuberculin, and that it should be standardised.

I feel acutely the disappointment of not having the great honour and pleasure of presiding at the meeting on Wednesday, and ask you to pardon my absence.—With very kind regards, your obedient servant,

JAMES CROWHURST, F.R.C.V.S."

Mr. H. P. HOBGEN seconded the Chairman's proposition, which was carried.

The HON. SEC. said he had received letters and telegrams from the following members and gentlemen who were unavoidably absent that day: Messrs. W. Caudwell, E. Morgan, J. Washford, C. W. Howard, E. M. Perry, N. Almond, Major Bolton, A.V.C., J. B. Martin, H. H. Jeffries, William Shipley, C. Morgan, C. F. Hulford, E. W. Morris, M. Moss, Charles Roberts, F. Robards, W. Pitcher, W. Coveney, Alex. J. Todd, J. Bell, and Prof. Wooldridge.

The HON. SEC. said, in reference to the letter from Mr. James Crowhurst, it was necessary for him (Mr. Toope) to make some explanation as to what had been done in the matter of the fees paid by insurance companies. Acting as secretary of the southern branch of the National Society, he brought the question before the general meeting of that Society in London on July 29th, and moved that the work done by the committee appointed by the National Council be accepted as the scheme the National Council should be directed to act under in future. Since last year he had been continuously writing to the insurance companies. A meeting of the general council of the National would be held in London about October 7th or 8th for the purpose of adopting a scale of fees recommended by the committee appointed by the Council of the National. The committee thought fit, when they met, to allow the insurance companies time to discuss among themselves before making any definite recommendation. That was in May. He wrote to eighteen of the companies telling them what was suggested, and asking them to consider the matter. Until a week or a fortnight before the general meeting he could get no definite information from them, and then they said they wanted until October. They had given the companies until October. He wrote them on September 5th, and he had received in reply a letter from Mr. Essex, who evidently in that matter was acting as general secretary to all the companies concerned:

"London, September 8th, 1913.

Dear Sir,—We have yours of the 5th inst., and are we to understand that it is the Committee of the National Veterinary Association that is to deal with the question of fees, or the Committee of your Branch.

As already intimated, the meeting of Insurance Companies will not take place before October, so that it will not be practicable to make any definite statement by October 1st.—Yours faithfully,

B. S. ESSEX, Managing Director,
Imperial Insurance Co."

He (Mr. Toope) replied:—

"National Veterinary Association.

34 High Street, Dover, Sept. 9.

Re Insurance Fees.

Dear Sir,—The Committee referred to in my letter is the special committee duly appointed by the Council of the National Veterinary Association, and these gentlemen have provisionally adopted the scale recommended by the South Eastern Divisional Society, which scale will be brought up for final adoption in its present form (unless modified after your suggestions), and all members of the veterinary profession will be requested not to act under any other terms.—Yours faithfully,

THEO. C. TOOPE, Hon. Sec."

The policy of the companies had been one of delay and the only way he could get anything definite from them was to deal with them as he had done. He was hopeful, in the next month or so, of having some definite arrangement far better than existed now. It would be some assurance to their President to know that they were still working, still acting in that particular line.

The HON. SECRETARY said most of them would remember that at the last meeting, just after the death of their friend Mr. Roberts, he was deputed to attend the funeral. He did so, and he received the following letter from Mr. Charles Roberts, dated May 31st:

"8 Church Road, Tunbridge Wells.

May 31st.

Dear Mr. Toope,—My relatives and I wish to express to the members of the South Eastern Veterinary Association our deep appreciation of their kind sympathy, and to thank them for the beautiful floral tribute which they so kindly sent in memory of my late father. Will you kindly convey this message at your next meeting.—With kind regards, yours sincerely,

CHARLES ROBERTS."

The CHAIRMAN said before commencing the business which they had to deal with on the agenda, the first of which referred to the working of the Tuberculosis Order, he should like, as their Chairman *pro tem* that day, to congratulate themselves on the very good attendance they had. He thought compared with other veterinary associations they read of in the periodicals, their attendance that day exceeded that of some other Societies. He thanked them for their attendance and expressed the hope that they would discuss, as far as possible, the matters on the agenda, which were of great interest, so that they might go away all the wiser for that meeting.

The Tuberculosis Order had only been in existence four months—a very limited time—but during that time he had no doubt the majority of them had had abundant opportunities of getting considerable experience as to the working of the Order. There were one or two points which struck him in his own experience which he would like to, draw their attention to as they were all important.

Firstly, in his opinion there was a want of proper and systematic inspection of cowsheds. There were many cases of tuberculous cows unreported—and they were likely to be unreported—because inadequate compensation was given to the owner. They could not be surprised under those circumstances that so few cases comparatively came under their notice. It was no good having an order compelling one to notify disease unless there were inspectors to compel the owners to do so. As to the compensation of three-fourths or one-fourth according to the post-mortem results, it was his experience that where a cow had been condemned and the owner got one-fourth of the amount of the compensa-

tion through the carcase being condemned, invariably dissatisfaction was the result. Where the compensation was put at £10, and the owner received a quarter (£2 10s.), he usually said "If I have any more cases I will take good care not to report them. I will get rid of the cows." He had a case where he valued the animal at £12 if it had tuberculosis, and £24 if it were non-tuberculous, knowing full well when he valued it that it would not pass the post-mortem examination, and that the carcase must be condemned. That caused a letter to be sent to him from Mr. Prosser stating that the Board of Agriculture wanted to know why he put such a high valuation as £12 on a tuberculous animal. He (Mr. Dixon) pointed out that the cow was giving three gallons of milk per day. He knew that the cow would be condemned and that as the net amount the owner would receive was a paltry £3, he did not think he had overvalued the animal. He would like to ask them what had been the best means of aiding them in diagnosing the disease, whether it had been by clinical, bacteriological, or biological examination, or by aid of the tuberculin test. He had had ten cases in the course of the four months. Of those, two cases were tuberculosis of the udder. Samples of the milk were taken and sent to the medical officer of health in both cases. One was positive and one negative. In both cases they reacted to the tuberculin test and both were condemned, and both carcasses were passed for food. Of the other eight cases one was diagnosed by clinical examination only and the carcase condemned. The remaining seven were condemned by the aid of the tuberculin test. Five were passed and two rejected. In one case of the five passed (a cow in the borough in which he passed the carcase) the sanitary committee would not sanction the use of the flesh for food as they said, as an authority of a health resort, they would not sanction the consumption of a cow that had been condemned by their veterinary inspector for tuberculosis. They therefore awarded to the owner three-fourths, and had the animal buried.

The HON. SEC. said a question had occurred to him in the course of carrying out the Order, and that was the difficulty of reporting the case when outside their district. He was looking at the question now from the private practitioners' point of view. He had three or four cases of tuberculous udder, two of which gave positive evidence on milk examination. Both of these animals were well bred and in good condition; in fact, one was fat with her third calf. He suggested to the owner that he should report the cases, and if he did not, he (Mr. Toope) would have to do so, as the owner said: "If you do, you don't come on my premises again." The Act said they must report, but would they do it for half-a-crown in the face of their client's opposition, who would go elsewhere? He should think twice before doing so. He should advise the owner to report, and in such cases stop the milk supply. He thought that was the only course they could adopt at the present time. That was looking at the matter from the veterinary practitioners' point of view. From the inspectors' point of view it was another matter.

A gentleman, who was a member of their Society, had called his attention to an advertisement in *The Veterinary Record* announcing the fact that a Dorking chemist undertook the milk examination for any veterinary surgeon who cared to send samples to him, and had informed him that some Surrey veterinary inspectors were doing so. He (Mr. Toope) maintained that it was a disgrace to the Surrey veterinarians if they were doing so, for the reason that they had this thing thrust in their hands and would not use it. They were unlike the Kent veterinarians who were asked to send their samples to Maidstone. In Surrey the thing was in their own hands, and yet it appeared they could not spend an hour to do the work and raise the profession

in consequence, but were sending the samples to an analytical chemist. He should like to mention names, but he thought he had better not. He should like it to go further, and for the meeting to say that they recognised that it had been done, but that they did not approve of it. They, in that Association, fought for the whole duties under the Act, and yet some seemed to throw away the chance of carrying out those duties when they had got them.

Mr. EMERY said when the market inspector went round the market and found an animal that was diseased he could have it transferred to the hotel yard, and send for the owner of the animal to see it, and if he were willing to have it killed he made no claim for compensation. The animal was sent straight away to the knacker's yard and destroyed. If the owner thought they were not dealing with him well, then the inspector had to give notice to the police and go through the usual form which entailed some trouble to all concerned. He thought the best way was to get the owner to agree to having the animal destroyed, and then as far as the valuation was concerned, not a farthing was asked. With regard to the statements that Surrey veterinary inspectors were going to Dorking to have their tests made, the previous week was the first time he saw the advertisement, and he was surprised to see it. The meeting could take it from him that none of the veterinarians from his district sent anything to Dorking to be tested. He knew that none of his neighbours did it, and he did not think it right to attach to them the stigma that they were incapable of doing their work, or that they had applied to some outsider, because it was not so. He did not wish it to go forth that they were not doing their duty to the Government, or to their clients and other persons. He could not take that in. (Applause.)

The HON. SEC.: I have the names of two who sent samples to Dorking.

Mr. EMERY: That is a small proportion.

Mr. GREGORY said with regard to the stopping of suspected animals in market, he thought it behoved them to be extremely careful. Since the Act had come in, he had had to stop four animals in a public market. He always took special care when stopping suspected animals to see that the sergeant on duty was with him who could bear out in evidence what he (Mr. Gregory) said. In the first instance he impressed on the owner that he did not condemn his animal as tuberculous, but that in his opinion she was in such a suspicious condition that he could not allow her to be sold. He thought if they did that, there would be no chance of an action being brought against them for wrongful detention, as the animal might be suffering from John's disease or some other wasting disease. In stopping animals in the public market they could not be too careful.

Mr. HIBBARD said with regard to the question of compensation, at a previous meeting it was pointed out that they must make a first valuation of the animal as being non-tuberculous, and in the event of the animal being tuberculous, he believed a quarter of that amount should be put down. At the time he remembered he suggested that it was then unknown whether the authority would consider the compensation to be paid was to be based on the higher valuation or the lower. No one seemed to know anything about it, but some time afterwards he had a case of two cows. He saw his friend Mr. Ebbetts, who said "Depend on it they will only give compensation on the lower valuation." That was his (Mr. Hibbard's) idea. He valued the animals at £22 and £23, and in the event of their being tuberculous at £5 10s. and £5 15s. On the result which was obtained by the tuberculin test they were destroyed. The carcasses were disposed of, after the tuberculous parts had been condemned, for £17. The compensating authorities pointed out that they suggested giving three-fourths on the lower valuation, namely, three-fourths

of £5 10s., and three-fourths of £5 15s., but they already received £17 for the carcasses. Was it fair that the owners should have that amount when the Council had already received £17? Unless he received some more information, what he contemplated doing in future was to value the animals on what he considered his client would get if the animals were tuberculous.

Mr. HUBAND said he would like to ask for his own information if it was a fact that under the Act an owner on being cautioned had the option of having his animal destroyed at once without compensation or whether having been notified he was compelled to allow that animal to go through the usual process of valuation, examination, and so forth. He had been reading a report in *The Mark Lane Express* of a case in which an owner, who was also the auctioneer in this particular case, had an animal in his market which the inspector stopped, and gave the owner notice that it was a suspected animal and ordered it out of the market. The owner did all he could to assist the inspector, but according to the letter, the animal was taken away and the owner offered to have it destroyed at once, and bear the loss himself, but according to his (Mr. Huband's) reading of the report, the owner was not allowed to do so. He would like to know whether it were universally allowed for an owner to save all further trouble to do as Mr. Emery had said and have the animal taken to the knacker's, have it despatched and let the matter come to an end. In the case he was referring to, the owner was willing to have the animal destroyed. The animal was tested on the same day and found not to be affected, but in spite of that, he was prosecuted for obstructing the officer in carrying out the Act and he believed was fined £3 and costs. He believed it was customary in one part of the country to allow animals to be destroyed should the owner wish it, and no further questions asked, and he thought that ought to be universal, but he was not sure if it was so.

Mr. GULLIFORD: That is so by the Order.

Mr. EMERY said in his friend's case the animals were so emaciated that they were not worth more than a £1. He thought that the farmer should have some of the benefit because farming was not the best of industries.

Mr. GREGORY said some six weeks previously he stopped a very emaciated cow in the market and had her put down in the corner, the owner not being there. He telegraphed for the owner, who asked him whether he could have the cow killed at once. He (Mr. Gregory) said he could. The animal was killed and taken away. He (Mr. Gregory) reported to the authorities what he had done, and he had heard no more of the matter, beyond the fact that he went down to the farm and examined all his stock to see whether there were any other cows affected: if the cow came from one district into theirs they must report it to the other district.

Mr. EBBETTS asked if the owner said he would have the animal killed, could they go and inspect the other animals on the farm?

Mr. GREGORY: Yes, because it came out of his herd at home.

Mr. EBBETTS: I did not know that we were bound to inspect the other stock at the farm.

Mr. GREGORY said it was in the Act that where an animal had just come from a herd, they must go and examine the other animals. He had done it and the county had paid him.

The CHAIRMAN said Mr. Huband's question was an important one. He thought there was no doubt that an owner had the right to have an animal slaughtered if he liked. He took it that a veterinary surgeon did not inspect all the cows. If he condemned one, or the owner chose to have it killed, the veterinary surgeon would have no *locus standi* to go round unless he went officially.

The HON. SEC. said if a case was reported to the veterinary surgeon then it was his duty to go, but if it was not reported then he had no right to go to the farm, so he read the Order.

Mr. DIER said he had a case of tuberculous udder come to market, and he asked the superintendent to serve a detention notice on the owner. It was agreed that the cow should go back, but the owner thought he could sell the cow there and then to the knacker. If he had, there was no possibility of knowing whether the cow was killed or taken away. The owner took it back and then rung up and said the cow had been taken home. He (Mr. Dier) took a sample of milk and said it was no doubt a case of tuberculous udder. The owner asked whether he was bound to let the police deal with the case. He (Mr. Dier) asked him if he would like to have the animal killed and he said he would. He told the owner that he considered it his duty according to the Order to examine the remainder of the herd. He did so and found another cow with a diseased udder. The owner, who was a good client of his, said he was sorry he had picked on that particular cow because it was his best milking cow, and said he was not satisfied with the microscopical examination, and asked him to apply the tuberculin test. He (Mr. Dier) said he did not think the County Council would object, and he applied the tuberculin test and got a distinct reaction. Mr. Dier mentioned that at the present time they did not know what fees the East Sussex County Council allowed them. The veterinary profession submitted a scale of fees, but they had heard nothing further, the County Council saying that they would hold the matter over until next quarter.

Mr. EBBETTS said he saw in the market an animal he suspected, and he told the owner who said he would have it killed. The animal was killed, but he (Mr. Ebbetts) was not aware that he was supposed to go and examine all the man's cows as well. He would like that point made quite clear.

Mr. DIER said if a cow that he suspected came to market from his own district he served a detention notice. If the cow went back to the owner's place, he took it it was his duty to go and examine the herd, but if the cow went into another district he notified that district and the inspector there went and examined the other cows.

The HON. SEC. said where they found a suspected cow in the market and the cow was taken back to the herd from which it came, he took it that it was their duty to follow it, but not so if destroyed when found.

Mr. HIBBARD said it seemed to him that the animals the suspected cow came in contact with were those in the herd from which the cow came.

The HON. SEC.: The law does not state that.

The CHAIRMAN said there was a way out of the difficulty. They did not want to suppose anything, and he thought the best way would be for the Secretary to write to the Board of Agriculture and ascertain in any case of doubt or difficulty what their powers were in that direction. He would move that the Secretary write to the Board of Agriculture for advice on any question of doubt that arose in the course of that discussion.

Mr. T. F. HOGGEN: Would it not be better to refer the matter to Mr. Prosser?

Mr. GREGORY said with all due respect to the Secretary, he could not agree with him that they had no right to examine the animals where the suspected animal had come from. They had the right, and if it were not stated in words it was implied. The animal he had referred to was a mass of tuberculosis, and within an hour had come right out of a herd of milking cows. He was acting officially as inspector, and as inspectors he contended that they were bound to follow up a case

thoroughly and examine the animals that it had been in contact with or the whole thing was useless.

Mr. EMERY said as local inspectors of the markets he did not think they had a right to follow animals to any premises.

Mr. GREGORY : It applies only to animals in inspectors' own districts.

Mr. EMERY : Then undoubtedly he has the right.

Mr. H. F. HOGGEN instanced cases that had come to his notice. One owner said the next time he should kill the animal himself and so not have all the trouble. That showed how some owners looked upon the working of the Act.

The HON. SEC. said if the suspected animal was killed outright where found, they were done with it, and they would not have to proceed further.

Mr. DIER said he thought by the explanatory letter that was sent to them they were supposed to examine the cows at the farm from which the suspected animal came if in their own district.

Mr. HIBBARD said if the animal was taken to another district then they had to send information to the inspector in that district.

Mr. GREGORY said it was their duty to state the number of other animals on the premises.

The HON. SEC. said if an owner destroyed at once a cow found in the market by an inspector, had the inspector power to visit the farm or cause the farm to be visited by another inspector provided the animal proved tuberculous. That was the real question raised.

The CHAIRMAN'S proposition, that the Secretary should write to the Board of Agriculture for advice on the points raised in the discussion, was carried.

JOHNE'S DISEASE.

ELMER EBBETTS, M.R.C.V.S., Rochester.

Mr. Chairman and Gentlemen,—Mr. Toope strongly impressed upon me the fact that a short paper was all that was necessary, so I am only going to point out a few facts: still, I hope that my remarks will lead to a good discussion, as I shall leave a lot to talk about.

For many years I have seen cases of John's disease, and for many years I have diagnosed them wrongly. A client would send to come and see a cow that was purging; on attending and asking questions one was invariably told that the animal had been suffering from diarrhoea for a long time. I used to think that I had a case of parasitic enteritis to deal with, or more often used to pronounce it tuberculosis of the intestines; anyhow, the case was most unsatisfactory as the patient never recovered. As time went on I heard of John's disease. I will tell you of one case which was the means of my first knowing the disease, the history of which will help to explain symptoms.

A client asked me to see a three-year-old heifer that was purging. I examined her, and fancied that I had a case of the then newly named John's disease. I told the owner my opinion and obtained his permission to have the heifer at my infirmary. By the aid of that most valuable test—tuberculin—I soon satisfied myself that she was free of tuberculosis. The symptoms were that the animal looked unthrifty, had a harsh coat, and continued diarrhoea, the faeces were of a frothy, bubbly nature, as if air had been pumped in, and had a fetid and very disagreeable smell. She fed well and ruminated naturally, but kept getting more and more emaciated.

I tried all sorts of remedies, but nothing did any good. After about three weeks I had her killed and made a post-mortem examination. Most of the organs were perfectly healthy, but on examining small intestine I found considerable thickening of the mucous membrane which I at first took to be chronic enteritis, but there was a peculiar corrugated, convoluted appearance which

was uncommon. I sent a portion of intestine to the College, and Mr. Sheather kindly wrote saying "I have examined the portion of intestine microscopically and find that it was undoubtedly affected with John's disease. The wrinkled appearance of the mucous membrane is characteristic of the disease, and this specimen is richer in the causal organism than any I have seen." I have here a portion of intestine taken from the same heifer, and as it is well preserved I hope it will interest you.

The disease is now known to be caused by a specific bacillus, which was first discovered by Professor John. Sir John McFadyen named it after the Professor, a pretty and well-deserved compliment. The causal organism enters the system through the mouth, taken in either with the grass or water, and is mostly, if not entirely, found located in the intestines and mesenteric lymphatic glands. I do not consider the disease very hard to diagnose, as we have tuberculin to tell us it is not tuberculosis, and the bacilli being present in the faeces makes the microscope a valuable aid. The bacillus greatly resembles that of tuberculosis, but this need not trouble us, as if we have no reaction to tuberculin we know that we have not the tubercle bacillus to deal with.

An animal may be affected with both diseases, then such a case would come under the Tuberculosis Order, as the animal would be emaciated. I know the disease is supposed to be highly contagious, but that is not my experience, as I have often had a single case occur in a herd: in fact, in a conversation I had with the owner of the heifer I had at my infirmary, he said he remembered the case well, but although he had had hundreds of bullocks since, he had never seen another. Sheep may, and in some districts do, become affected; I wonder if the cases of emaciated sheep we often see may not sometimes be due to it. The incubation period is supposed to be long, sometimes a year or more, but this is not always the case as I have seen it in a yearling. So far no curative remedy has been found, but I believe a product of the bacillus has or will be made that will help diagnosis as tuberculin does.

Well gentlemen, I have told you nothing you did not know, and no doubt many of you know a great deal more about the disease. Such being the case, I hope we shall have a good discussion. I thank you very much for the kind way you have listened to my few remarks, and if you think such as these are worth reading, I am sure Mr. Toope will have no difficulty in getting plenty of papers.

DISCUSSION.

Mr. HUBAND said his experience was entirely in accord with that of Mr. Ebbetts. He believed it was Sir John McFadyen who confirmed the existence of that particular disease. It explained to his mind, as it did to other practitioners in country places, and was a satisfactory explanation of the difficulty they had in cases known as piners—which word indicated the condition very well. The essayist had put it very clearly and in a practical manner. He was sure one of the advantages of such an Association as theirs, was that every member of the profession could be fully acquainted with every recent discovery in connection with the profession.

Mr. J. BASIL BUNTON : I rise, sir, in response to your invitation, but I fear that I have nothing to add which would be of interest from a clinical standpoint. John's bacillus, as is now well known, will grow on various special media, such as those containing the dried ground-up bodies of dead human tubercle bacilli or bacillus phlei with egg and mace, and later in glycerine liver or beef broth. After prolonged subcultivation, this organism will grow quite easily on the surface of ordinary glycerine agar or brain agar. When it has acquired the property of growing on these media, the

growth tends to lose its moist appearance (resembling tubercle bacilli of the avian type) and to assume a dry and sometimes hard character, resembling in some cases very closely the method of growth of tubercle bacilli of the human, or even bovine types. With regard to the diagnosis of John's disease, there seems to be good reason to believe, as a result of the valuable work which has recently been done, that at an early date a diagnostic agent will be prepared which will be as specific for this disease as tuberculin is for tuberculosis.

Avian tuberculin, which was once recommended, has now been practically discarded. It was found that a tuberculin prepared from strains of tubercle bacilli from the lower animals (bird or fish) would, if used in sufficiently large doses, give reactions in tubercular infection of mammals. Further it was shown that ordinary broth when injected in similar quantities would produce a rise in temperature similar to that of the tuberculin. The more recent diagnostic vaccine, as it is called, has apparently given more satisfactory results, but there even yet seems room for a more perfect agent. It seems reasonable to suppose that when this organism can be induced to grow freely under conditions which are favourable to it, its metabolic products will be as specific in diagnosing this disease as the metabolic products of tubercle bacilli are in diagnosing tuberculosis. From the evidence available from various laboratories it would appear that the agglutination and complement fixation tests would prove of even greater help in diagnosing the complaint.

As to the cure of the disease, I have no doubt that at an early date there will be several curative vaccines on the market, but before any conception of their value can be formed, an enormous amount of experimental work will have to be carried out.

The SECRETARY said he met with the disease some years ago, when he was in Yorkshire, and like others, he attributed it to a form of tuberculosis of the bowel. In some districts it was exceedingly rife in some years; in one valley he got from twenty to thirty cases, then for a year or two he would get but few. He had never seen it in an animal under three years' old. One very old farmer told him it had been recognised as existing occasionally in that district for years; he called it "blind scour," and the animals affected were known as "wastrels" or "skiters." Once having diagnosed the disease, the veterinarian's services usually ended, the owner usually said, "If it gets no better in a week or two, I will have it destroyed"—a wise solution generally.

Two cases have come under notice during the past eight months, and in neither had he any great difficulty in diagnosis, during life or post-mortem. In some cases of emaciation Sir John M'Fadyen advised a double test: first with ordinary tuberculin, and if no reaction is obtained, a second test with Avian tuberculin; if the second reacts there is some proof that John's disease exists.

Another method is by subcutaneous injection of Avian tuberculin, and the simultaneous ophthalmic test with bovine tuberculin. If the eye reaction were well marked, they could conclude tuberculosis was present; if the other reaction occurred, they could conclude John's disease was present.

The lesions in the early stages were small and not always easily made out, and confined to the mucous and sub-mucous structures, generally of one section of bowel only, and the lower third of it: lesions later appeared in the larger bowel, and only when diarrhoea had set in did they find much indication of corrugation of the bowel. In many cases emaciation was marked before the diarrhoea appeared to be excessive. He had a case now which, although it had reacted to tuberculin, he thought might possibly be associated with John's disease from its previous history.

Another point was that John's disease was very rarely associated with pulmonary indications or a cough, whilst only very rarely was tuberculosis accompanied with diarrhoea. These two facts were of much clinical importance. Both diseases could, and did, exist at the same time, and when so, we got the characteristic tuberculin reaction unmodified.

When both existed they could distinguish the separate lesions after death, because John's was confined to the bowels and their glands (only once had it been found elsewhere), the lesions too being free from caseation or calcification, which was never found in John's disease.

As our essayist has pointed out, there is another disease which causes emaciation on a persistent diarrhoea (and one frequently met with in my district), due to the presence of the strongylus convolutus in the fourth stomach. It is confined to young animals, generally under eighteen months' old, but on one occasion I saw it in several older ones, from drinking from an infected pond, their only source of water being surrounded by a veritable bog.

If one adopted Avian tuberculin in diagnosis, a larger dose was required, and the temperature chart would not read so high as with bovine tuberculin in tuberculosis.

The CHAIRMAN said little or nothing had been said about the treatment, which was the principal thing that concerned most of them.

Mr. BUXTON said he thought it was quite possible that before many months, a metabolic product would be introduced with that end in view, but it was not yet perfected as far as he knew.

Mr. GREGORY said he had always been puzzled about the disease, which he had known for many years. He thought their scientists might be able to prepare a vaccine that would counteract the disease. That was an instance in which the Government ought to help in a considerable degree, but he was afraid it was useless to hope for much in that direction.

Mr. EMERY said in the west of England the profession largely used sulphate of copper, and other tonics without much result.

The CHAIRMAN proposed a vote of thanks to Mr. Ebbetts for giving them an essay on that important disease. They were greatly indebted to Mr. Ebbetts, and he thought it would be an inducement to the other members to read papers to the Association, and he hoped they would all have the opportunity to further the interests of that Association by bringing forward interesting matters.

Mr. H. F. HOGGEN seconded the vote of thanks, which was carried unanimously.

Mr. EBBETTS, in acknowledging the compliment, said it was a pleasure to him to do anything to further the interests of the Association. He had only written a short paper, but he thought a good discussion on a short paper was all that was necessary.

New Member. Mr. GERALD WACHER was elected a member of the Association on the proposition of Mr. Gillard, seconded by Mr. Dunkin.

Next Meeting. The SECRETARY said the next business was to select a place for the holding of the next meeting, which would be their annual gathering, and he hoped it would be a social function, and that the members would bring their wives and lady friends. It was suggested at their first meeting that the meetings should be held in East Kent and West Kent alternately, and he thought for the next meeting they could not find a more central place than Tunbridge Wells, where they had a very good meeting the last time they went there.

On the proposition of Mr. Dier, seconded by Mr. Emery, it was decided to hold the next meeting at Tunbridge Wells on the second Thursday in January, 1914.

SPECIMENS AND CASES.

The CHAIRMAN produced the heart and the two kidneys of a young heifer. The general condition of the heifer was such that it was apparent that it had some organic trouble, and the owner decided to have her destroyed. In comparison with other heifers she was not half the size. The post-mortem proved tuberculosis of the kidneys.

The Chairman also brought a large tumour, weighing over a pound, which he took from the flank of a cow; also a piece of wire which he took from the rectum of a dog.

Mr. W. H. CROWHURST produced an interesting specimen of a hoof and diseased pedal bone.

Mr. H. F. HOBGEN told the meeting of a polled Angus cow which he was called to attend. He explored and found the two fore legs, and one other—a hind one. He fixed cords on and attempted to withdraw the calf which was dead, but he could not get it out because he found this hind leg would come up. Eventually he got the head and fore legs out as far as he could and put a strong rope round its neck, and withdrew the calf. He found that the trouble was due to its being deformed from the region of the spine and one of the hind legs. He had brought a portion of the calf for the inspection of the members.

Mr. DIER exemplified the recuperative power of some animals by the case of a small terrier bitch that his partner had attended. The bitch, he said, had been trying to whelp for two days, but could only get away a portion of one shoulder, and then the lower quarter. He accompanied his partner, and he told the owner that it was a hopeless case, but that if he chose he would do what he could with Caesarean section. The owner would not decide then (Friday), and although he asked the owner twice to allow him to operate he would not decide to have an operation until the Thursday following—and yet the owner called it a favourite bitch. (Laughter). He injected two grains of morphia. He exposed the fetus, but he was afraid the bitch would collapse during the operation. He might say he was taking the same pains that he would have taken if he thought the case was going to be successful. After the operation he put the dog in a small box and the next day it looked up. They offered it beef tea and it started lapping. In a fortnight the wound had healed up, and at the present day the bitch was running about as well as could be.

Mr. HUBAND said on the previous Monday morning he was turning out at eight o'clock when he was informed that a cart horse of his was nearly dead. He went down to the field and found the horse had commenced ploughing when he went into a state of collapse. Evidently he had an obstruction in the throat. He had nothing but a pocket knife with him, but with it he opened the trachea. He held it there for a short time until the horse plunged about and a considerable quantity of frothy mucus was ejected, mixed with blood. Much to his surprise the noisy breathing became less marked, and in a short time the horse recovered. No doubt he ruptured a blood vessel in the lungs. If he had not had some knowledge of the science of which they were all so fond he would have lost the horse.

In conclusion, Mr. Huband proposed a cordial vote of thanks to Mr. Dixon for the able manner in which he had presided that day. They all deplored very much indeed the sad reason that caused the absence of their genial President, but he was sure they would all agree that they could not possibly have a more excellent or efficient substitute. (App.)

The SECRETARY, in seconding, said he was very pleased when Mr. Dixon responded to the call.

The vote having been carried unanimously, Mr. Dixon made a brief response, in which he said he only

regretted the cause of his having to take the chair that day.

A large selection of microscopic preparations of John's disease, tuberculosis, anthrax, glanders, and other bacilli and their lesions from the collection of Messrs. Dixon, Morris, Toope, and others, were exhibited in the room, and were inspected by the members in the limited time at their disposal after the discussion. That the branch of study deserves more attention at society meetings was the opinion generally expressed.

THEO. C. TOOPE, Hon. Sec.

The Ration of the Troop Horse.

The troop horse's ration is 12lb. of hay, 10lb. of oats, and 8lb. of straw (or its equivalent) per diem. Everyone is aware of this fact (says the *Army and Navy Gazette*) and everyone is equally aware that it is insufficient. Every horse-master knows that it is impossible to expect any horse to work well and look well on such a miserable allowance. It is meagre enough for the aged horse doing his legitimate work, and it is still more so for the remount, who not only has to be trained, but has to develop bone and muscle. "It is a miserly and short-sighted policy to treat our Government horses thus, because it is not even economical. A horse, when insufficiently fed, breaks down under the strain of hard work and swells the ranks of the unemployed in the sick lines and the lists of horses for casting. If only five fewer horses per regiment were cast every year it would represent a saving of not only the difference between purchase and sale price, which would be about £150, but also the forage and attendance necessary for them when they were sick and unable to earn their feed." And yet an extra £150 per regiment, adds the writer, would go far in helping the forage account and in making regiments more efficient for war.—*Horse and Hound*.

Personal.

THEXTON—ALEXANDER.—On September 3rd, at St. George's Church, Kendal, Percival Thexton, M.R.C.V.S., of Pontefract, to Jeannie, second daughter of Mr. Wm. Alexander, of the Homestead, Kendal.

Mr. G. P. MALE has been invalided with trouble of the appendix.

Mr. HARRY REDFORD is still feeling the effects of his accident in July, and is unable to take up his full round of duties.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Sept. 16.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

Lieut. W. T. Brookes resigns his commission. Dated Sept. 17.

Sept. 12.

REGULAR FORCES. ARMY VETERINARY CORPS.

Major W. A. McDougall, F.R.C.V.S., retires on retired pay. Dated Sept. 24.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

Maj. W. A. McDougall, F.R.C.V.S., retired pay, Reserve of Officers (late of the A.V.C.), is appointed Assistant Director of Veterinary Services of a Territorial Division; Maj. McDougall is granted the temporary rank of Lieut.-Col. in the T.F. whilst holding the above appointment. Dated Sept. 24.

OBITUARY

WM. CHAS. ISON, M.R.C.V.S., Atherstone, Warwickshire.
Graduated, Lond: May, 1860

Mr. Ison had been in practice at Atherstone since 1860 up to his death which occurred on Sept. 23rd. He was 73 years of age.

Much regret has been occasioned in Salisbury by the death of Mrs. Harding, wife of Mr. E. R. Harding, Veterinary Inspector to the City Authority. About two months ago Mrs. Harding underwent an operation for appendicitis, and was making a good recovery when she was unexpectedly seized with paralysis. Her condition encouraged the hope that she would recover, but on Sunday morning, 14th inst., another seizure proved fatal. Mrs. Harding came to Salisbury on the occasion of her marriage nearly 25 years ago.

The funeral took place on Wednesday afternoon at the Devizes Road Cemetery amid many signs of sorrow and respect.—*The Salisbury Times*.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1318.

OCTOBER 11, 1913.

VOL. XXVI.

PITUITARY EXTRACT.

Many, and indeed most therapeutical innovations fail to justify their introduction into practice: but pituitary extract seems very likely to gain a permanent place in veterinary obstetrics as a uterine stimulant.

Here and abroad, it has given remarkably good results in uterine inertia in the bitch—probably the animal most frequently affected with this difficulty in parturition. Recently, upon the Continent, it has been found equally successful in the case of the large farm animals. The agent seems to act equally well upon either an originally inert uterus or one which has become inert only after severe and ineffectual labour. It seems to be as reliable as the most accurately standardised preparations of ergot; and no ill effects have yet been reported from its use. Its record, so far, suggests that it will prove the best uterine stimulant we possess; for none of the old ones are altogether satisfactory.

Both English and Continental firms now prepare pituitary extract, and only one objection, and one warning apply to its use. The objection is that it is expensive. This should not deter us, for the agent is not required for everyday use, but for special cases in which it may prove indispensable. The warning concerns the possibility of toxicity. The comparatively few reports of the drug now available indicate that it is surprisingly free from injurious effects, but these must not be taken as final. We doubt whether an extended experience will confirm the view that the agent is entirely devoid of danger.

GLANDERS.

Again this week, for the second time in history, the Board of Agriculture returns show that no case of glanders had been reported in Great Britain during the preceding week.

Mr. W. Hunting, who has been ill for several weeks, is still confined to his room and is unable to attend to business.

He has been suffering from suppurating inflammation of the left ear, and the violent pain ensuing has quite prevented him from either reading or writing. His condition has caused great anxiety to his friends and relatives, and it is probable that he will not be able to resume his correspondence for another week or so.

POISONING BY BARIUM NITRATE.

The subject was a thoroughbred mare called "Chouta" by "Lancers" ex. "Phryné."

In the morning of May 2nd, 1911, a boy was sent to me asking me to send a remedy for this mare for a slight cough. I sent the following recipe:—

R Chlorate of potass.	30.00	grams.
Nitrate of potass.	30.00	"
Glycyrrhiza	30.00	"

This quantity for one powder. One powder to be given twice daily in the food. The prescription was sent at 10 a.m. to a chemist who made up one dozen of the powders.

A powder was given by the owner at 12 noon, followed by effects indicative of slight colic. Another was given about 6 p.m. in the evening feed.

At 9 p.m. the owner came to me to tell me the mare was very seriously ill with colic, so I went at once to see her. It was a matter of 15 kilometres drive over very rough roads, so I didn't arrive until 10.30 p.m. The mare was then dead, so I opened her. The stomach was quite normal also the first part of the duodenum, but the small intestine from behind the entrance of the bile duct was very much injected, one can hardly say inflamed, for the appearance was more or less like a venous congestion, and in direct contrast to the parietal peritoneum. Further, the mucous membrane of the intestine was not inflamed as one would expect with an irritant poison.

My client at first said my prescription was bad, and the following day gave one of the powders to a colt of his fresh from grass. This colt suffered from diarrhoea for more than a week after. My client then took the prescription to another chemist and tried these powders on another colt who had a cough, with good results. After this he tried one of the original powders, with the same result of colic and diarrhoea.

This decided him to consult me again, and I suggested to analyse the original powders, also the contents of the intestines of the mare "Chouta." These were sent to the Instituto Higiénico Nacional de Chile, with the following results. The powders were composed of:—

R Chlorate of Potass	30.00	grms.
Nitrate of Barium	30.00	"
Glycyrrhiza	30.00	"

The intestines revealed the presence of barium in considerable quantities.

I send you this clinical note more from the rareness of encountering mineral poisoning in herbivora with authentication of its source, and also the peculiarity of not encountering any congestion in the duodenum before the bile duct, deducting from this that the bile may have a dissolvent action on salts of barium. A case for compensation against the chemist is now in the courts. According to South American Republican custom the result will be known in 1930 or thereabout.

Santiago, Chile. WM. J. MOODY, F.R.C.V.S.

AMPUTATION OF THE LIMB IN A COW.

The subject of the photograph is an Ayrshire quey, aged two years, the property of Mr. Wm. Steel, Hazeldean Farm, by Strathaven, Lanarkshire.

The quey was found in the field on Feb. 2nd, with fracture of the off fore canon bone. It was

taken into the house and the leg put in splints, a dry dressing was applied every alternate day until the operation wound healed.

An artificial limb was fixed on on March 21st. Slight improvements have been made on it since, but it consists essentially of: two iron splints attached to a round piece of wood below, and to the limb below the elbow by a broad band of leather which is laced tightly. The end of the limb is inserted into a leather pocket and rests on a felt pad.

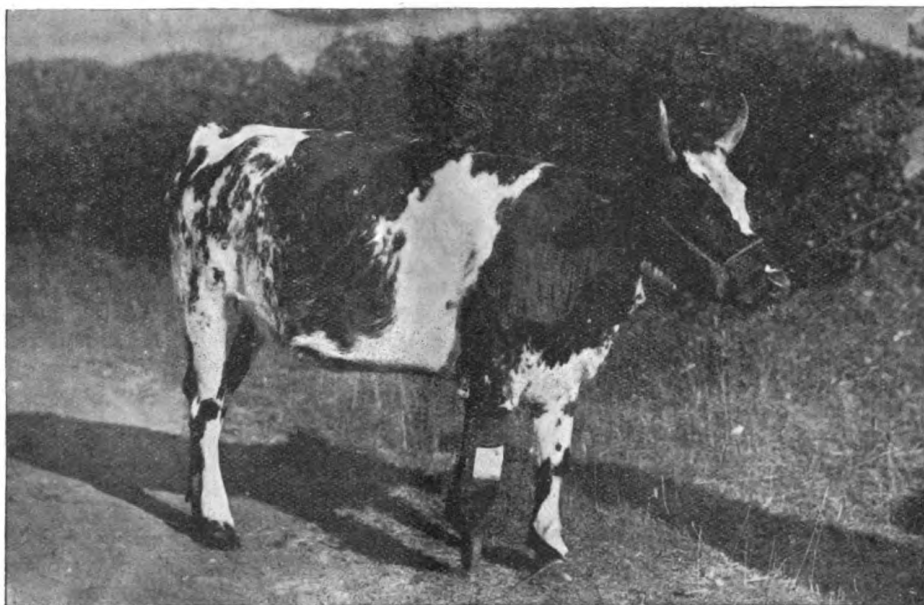

The quey is in prime condition and enjoys perfect health. It can use the leg well, is able to lie down and rise, and can run with the rest of the cattle.

The operation was performed by myself and my assistant, Mr. James M. Galloway, Class D.

As I have not seen anything of the kind recorded for some time, I thought it would be of interest to the readers of *The Record*.

PETER MEIKLE, M.R.C.V.S.

Strathaven.

ABSTRACTS FROM FOREIGN JOURNALS.

AN ENZOOTIC AMONGST YOUNG PIGS CAUSED BY A VARIETY OF THE STREPTOCOCCUS PYOGENES.

Prof. Rievel, of Hanover, records (*Deutsche Tier. Woch.*) an enzootic which occurred upon premises, which, for four years past, had been free from contagious diseases of swine. Numerous cases of illness and death appeared suddenly amongst the young pigs, affecting those which were housed in old draughty pens composed of framework; while the animals which were in new, well-made pens, remained healthy, although they associated with the sick ones on the same exercise ground. The mortality amounted to 50%. The old pigs remained unaffected.

Amongst the most prominent symptoms seen were lentil-sized reddenings, which afterwards became covered with brown-red or black crusts, upon the under part of the abdomen and the inner surface of the thighs. There was also conjunctivitis with a considerable muco-serous discharge, which often dried into crusts. The general condition was little disturbed, and the temperature ranged between 103.6° F. and 104.9° F. Death occurred suddenly and without warning, after a period of illness which varied in duration.

Post-mortem, a number of lesions were found, in addition to those of the skin and eyes. Generally there was a large quantity of sero-fibrinous fluid in the abdominal cavity, slight swelling of the spleen, and degeneration of the liver and kidneys. The liver and kidneys also showed isolated or

numerous hæmorrhages. In all cases there was slight reddening of the small intestine, and often also small superficial hæmorrhages in the cardiac portion of the stomach. The thoracic cavity contained a serous fluid which was rich in fibrin elements. The heart muscle was slightly opaque, but the lungs showed no pathological alterations.

Bacteriological examination revealed diplococci in the organs, in the blood, and especially in the fibrinous exudates. Ohlenbusch classifies this diplococcus as a variety of the *Streptococcus pyogenes*. This species of streptococcus is very resistant to cold and to desiccation, and is pathogenic for young pigs, mice, rabbits, guinea-pigs, and pigeons.—*Berliner Tier. Woch.*

THE ACTION OF PITUITARY EXTRACT UPON SOWS.

Walther Gottschalk, of Brunsholm, writing upon this subject, points out the admitted uncertainty of the emmenagogues hitherto employed, and the fact that weakness of labour pains is common in the sow and not rarely necessitates slaughter. These considerations have induced him to try the pituitary extract prepared by the "Chemischen Fabrik" of Aubing (*vide Veterinary Record*, Sept. 27th, 1913, page 199) upon sows, and his results from it have been highly encouraging. So far, he has only treated four cases, which he reports as follows.

This first case was a sow which had given birth to one dead foetus, and had afterwards lain a long time in the pen without labour pains. Gottschalk injected 5 c.c. of pituitary extract subcutaneously. Fifteen minutes later, as the drug had had no effect, he again gave the same dose, but this time administered it intramuscularly in the forelimb. After another fifteen minutes vigorous labour pains set in, and led to the birth of the three remaining young—one living and two dead. The sow did well.

The second case was a sow from which Gottschalk had already removed one living foetus with the forceps. Thinking it possible that others might be present, he injected 10 c.c. of pituitary extract without effect. Half-an-hour later he again gave the same dose intra-muscularly; but, though he remained watching the sow for a full hour afterwards, he saw no sign of labour pains. It transpired that no other offspring were in the womb, and in this case, therefore, the drug failed to induce uterine contractions in the absence of a foetus. The sow and the one young pig did well.

In the third case the sow gave birth to nine living young without assistance, after which a macerated foetus lay for 36 hours in the birth passage, despite all efforts to remove it with the forceps. Labour pains were completely absent. The intramuscular injection of 10 c.c. of pituitary extract induced vigorous and persistent pains in fifteen minutes, leading to the delivery of the foetus. The sow was slaughtered next day on account of threatening metritis.

The fourth case was a sow in which a living foetus could be felt in the birth-passages, but labour pains were absent. The subcutaneous injection of 10 c.c. of pituitary extract was followed after about

25 minutes by vigorous and persistent pains, which resulted in the birth of three living young in the course of an hour. These three were the whole litter. One of the young died, the two others and the sow did well.

Few as the cases are, Gottschalk believes them to justify the conclusion that pituitary extract is of great value in all cases in which the labour pains of the sow partially or completely fail. He has never seen any ill effects from its use, and on that account is inclined to regard it as quite devoid of danger. In future, his intention is to use it in doses of 10 c.c., administered *intra-muscularly*.—*Berliner Tier. Woch.*

AN AGENT FOR USE AGAINST RATS.

H. Novak, a gardener, announces (*Thüringer landwirtschaftl. Zeitung*) that the common hound's tongue (*Cynoglossum officinale*) is a certain agent to secure the banishment of rats. The plant is found on rubbish heaps, in fields, etc. The purple flowers have an unpleasant odour. The freshly dried plants drive away rats by their odour; and, when strewn in a place infested by rats, they are said to cause the immediate departure of the animals. Stuffing the rat holes with the plants will cause the rats to migrate further and more completely.—(*Münchener Tier. Woch.*)

W. R. C.

[*Cynoglossum officinale* is found in some parts of the United Kingdom; but those who think of using it for this purpose should remember in doing so that it is credited with being poisonous to farm animals on account of its contained alkaloid *cynoglossin*, which resembles curare in its action.—*Transl.*]

THE NUMBER AND VARIETIES OF BACTERIA CARRIED BY THE COMMON HOUSE FLY IN SANITARY AND INSANITARY CITY AREAS.—G. L. COX, F. C. LEWIS, and E. E. GLYNN. (*Jour. Hyg.* (Cambridge), 12 (1912), No. 3, pp. 290—319, pls. 2, figs. 2.

"Over 450 naturally infected or wild flies (*Musca domestica*) were caught in Liverpool during September and the first part of Oct., 1911, from different parts of the city. The number and kinds of bacteria carried and contained by them have been investigated. The number of bacteria coming from house flies whilst struggling in liquid may be very large, varying from 2000, the lowest figure in five minutes, to 350,000, the highest figure in thirty minutes. This number may be taken as a measure of their capacity to pollute liquid with their vomit or excrement, or by wallowing in it. The number of bacteria carried inside the fly is very much greater.

"Flies caught either in insanitary or congested areas of the city carry and contain far more bacteria than those from the more sanitary, less congested or suburban areas. The number of aerobic bacteria from the former varied from 800,000 to 500,000,000 per fly, and from the latter from 21,000 to 100,000. The number of intestinal bacteria as indicated by glucose bile salt fermenters

is also greater in the insanitary or congested areas, the numbers varying from 10,000 to 333,000,000, than in the more sanitary areas where they carried from 100 to 10,000. Pathogenic bacteria and those allied to the food poisoning groups were only obtained from the congested or moderately congested areas and never from the suburban areas."

THE HOUSE FLY AND ITS RELATION TO CITY GARBAGE.—J. H. PAIN (*Psyche* 19 (1912), No. 5, pp. 156—159).

In investigations conducted in a Boston tenement district the author found various species of muscids, including a large percentage of house flies, swarming about garbage, depositing eggs and feeding upon it and upon other refuse thrown into the alleys. Larvæ were collected from the contents of various pails as they were emptied into the carrier's wagon, being as a rule found in quantities and often so abundant that the interior of the receptacle appeared as a wriggling mass. They were taken to the laboratory and placed in covered boxes containing a little earth in which they could pupate, and were fed upon stale water-soaked bread. Of 649 specimens reared to adults, 22.4 per cent. were *Musca domestica*, 22.3 per cent. *Phormia regina*, 50.5 per cent. *Lucilia serricata*, 4.4 per cent. *Calliphora erythrocephala*, and 0.1 per cent. *Muscina stabulans*.

THE HOUSE FLY AS A CARRIER OF TYPHOID INFECTION.—F. W. THOMSON. (*Jour. Trop. Med. and Hyg.* (London), 15 (1912), No. 18, pp. 273—277).

This is a report of investigations made at the Central Research Institute of India. The experiments led to the conclusions that "the ingestion of typhoid germs in large numbers has no bad effect on the health of flies; they can retain living typhoid bacilli within their bodies and transmit infection thereby for a period of 24 hours after ingestion; they can carry the living germs on the exterior of their feet or bodies for a period of six hours, and so transmit infection. F. E. P.

ROYAL (DICK) VETERINARY COLLEGE.*

Address by Dr. O. CHARNOCK BRADLEY, M.D., D.SC., CH.B.
Principal of the College.

He who has the privilege of giving an address at the opening of a new session, has a roving commission. He is at liberty to choose any subject which seems to him good, provided always that it must be cognate and should be topical. On the present occasion there is no dearth of subjects upon which to draw, the only difficulty being to decide which is most fitting.

The consideration of tuberculosis in its many aspects would be appropriate. Here is a disease rampant in this country, widespread in its distribution, affecting all classes, sparing neither man nor beast, causing untold misery among the human race, and producing enormous pecuniary loss to the owner of animals. That such a disease should occupy the thoughts of those who guard the health of the community, and those solicitous

of the commercial welfare of the country is natural. That the public should desire prompt, entire, and final elimination of such a scourge is natural. That they should evince some degree of impatience at what, to them, appears the slow operation of preventive and curative measures is not surprising. But here, as in the case of other specific diseases, slow and sometimes tentative measures are imperative. A disease like tuberculosis cannot be eradicated on the instant, and this for reasons which are sufficiently obvious. Therefore, one must counsel patience and an endeavour to rest in the assurance that everything which is humanly possible and economically expedient is being done to bring about a time when tuberculosis will be a thing that was and is not.

So far as the recently introduced Tuberculosis Order is concerned, it is yet too early either to praise or to condemn. Time alone will demonstrate all its merits and demerits; but, whatever these may be, the Order is commendable if only in that it seeks to remove those cases of bovine tuberculosis which are of most danger to man. It is much to be regretted that the unfortunate Milk and Dairies Bill has failed to pass through the various Parliamentary stages necessary to make it law. There are those, I imagine, who will claim greater importance for this Bill than attaches to other measures which received more attention by Parliament during the last session.

Another disease which might quite fittingly have formed the subject of this address is that, up to the present, somewhat mysterious illness of sheep which rejoices in the possession of the decidedly inelegant name of "scrapie." The very fact that it has not, as yet, received a polysyllabic title is significant. Unlike tuberculosis which has no geographical limits and affects man as well as animals, "Scrapie" is limited in its distribution, and is confined to sheep. Nevertheless it is a disease of great commercial importance, and the sheep-owners of the South of Scotland have reasonable cause for anxiety to know how it is caused and spread, and how its ravages can be combated. Unfortunately "scrapie" has a long period of incubation and, consequently, investigation is slow. Though several observers have made it the subject of careful study, they are not as yet agreed as to the cause. Until this has been decided it will be difficult to suggest adequate and certain preventive measures.

I am well aware that the agriculturist is apt to think that investigation into the cause and prevention of diseases is slower than need be. May I seize this opportunity to point out that discoveries of importance are of necessity slow. If the conclusions arrived at are to be of any value, the various steps of an investigation must be repeated and checked more than once. Those who have most experience of research, and whose word is consequently of most worth, have learned from experience the importance of extreme care and wariness, and are alive to the dangers of taking anything for granted, and of pronouncing judgment hurriedly. The scientist knows that, as other men, he is fallible, and so desires to follow that line of procedure which will help him to avoid mistakes. This is all really to the advantage of the stockowner. A hasty, ill-considered statement might do more harm than good.

I know, also, that some agriculturists are of opinion that the practical farmer is not sufficiently consulted. In answer to this it is enough to say that no investigator worth his salt neglects any information from any source which is likely to throw any light whatsoever upon the problem he is endeavouring to solve.

The importance of tuberculosis, "scrapie," and other diseases of a like nature notwithstanding, it appears to me that, for several reasons, the present is a fitting occasion on which to scan quickly, and therefore super-

* At the opening of Session, on Wednesday, Oct. 1. Prof. Rankin, F.R.C.V.S., in the chair.

ficially, the aims and methods of those who, at the present day, are charged with the training of the future professional man. I propose, therefore, to lift the curtain ever so little and allow a glimpse of the aims and methods of the staff of a college like this.

The cynic has said that educational matters never did interest the British public. This may have been true once, but one would hesitate to make so sweeping a generalisation to-day. The average citizen has his own views on elementary education at least, though possibly these views may not accord very perfectly with those of the professed educationist. And there are not wanting those who follow closely the progress of secondary education. Professional education, however, is generally considered to be something apart, something so highly specialised as to be beyond the comprehension of the everyday person. As a matter of fact the aims and methods of professional education have the same root ideas as have those of elementary and secondary education. There is no reason why the average citizen should not follow sympathetically the ideals underlying the training of the professional man, and there is every reason why he should. A profession and the public act and react upon each other. It has been said, and said truly, that the level of a profession depends, not so much upon its members, as upon the intelligence of the average citizen. If the public were to demand a higher standard of attainment in their medical attendants and veterinary surgeons, it is safe to say that that standard would have to be achieved. It is therefore in the interests of the public that they should keep themselves *au courant* with the aims and methods of professional education. It is to be remembered that it is simply to safeguard the public that degrees and diplomas are granted to the medical man and the veterinary surgeon after passing certain tests. The citizens, therefore, are merely doing their duty to themselves when they enquire as to what these degrees and diplomas are, what tests are imposed upon the candidate who seeks them, and what training the candidate has undergone in preparation for the tests. Concerning diplomas and degrees little need be said here, except that the advance of the veterinary profession is indicated by the fact that now the Universities of London and Edinburgh grant degrees in veterinary science to those who desire the higher scientific training. In instituting veterinary degrees these two Universities doubtless earned the disapproval of Sir Alfred Hopkinson, who, the other day, expressed the hope that at some not distant date some indiscreet but intelligent person would propose the abolition of degrees altogether. I think we may safely assume that medical and veterinary degrees will never be, and cannot be, abolished, since they serve as a hall-mark whereby the attainments of the possessor are indicated.

There is another aspect of professional education which is, I think, far too often ignored. The citizen who has undergone an adequate and sound training of a technical kind has gained both morally and intellectually. Indeed, Sir Philip Magnus recently claimed that science and the application of science to industry and professional life gives quite as good an intellectual training as the more literary studies of the older universities. In Scotland, where the "humanities" have ever been revered, it is perhaps too much to expect that all this will be accepted as a truth. But it is incontestable that the man with a professional and scientific training, apart altogether from his ability to apply his knowledge professionally, is a more valuable citizen than he would have been otherwise. By producing such citizens, therefore, schools of applied science are performing a civic function as well as a professional one.

As a teaching institution we are concerned with the manner and effect of the training of the student rather than with the granting of a diploma or degree as the goal of his curriculum. The manner of the training has

undergone considerable change of recent years, in accordance with the trend of modern ideas on education generally. That educational ideals and practice should change is in the natural order of things. Fortunately man is a mixture of conservatism and progressivism—a dweller in the "double house" of the Egyptians, a driver of the two horses of Plato. And man discovers new wants and feels new aspirations. He evolves mentally. What was good enough for his father is most certainly not good enough for him. So his views on education widen and deepen. It is thrice fortunate that this is so, for there is grave danger in being satisfied.

Education, moreover, is in its essence progressive, nay, it is more, it is anticipatory. However strongly this applies to training in elementary and secondary schools, it applies yet more strongly to scientific and professional education. Consider the great and rapid advance in science generally during the past quarter of a century, and there is no wonder that methods of teaching have altered. While other arts and sciences have been forging ahead, veterinary science has not stood still. Both as a science and as a profession, its development has been remarkable. Not much more than sixty years ago, the veterinary surgeon in Scotland was generally a working man who, for two sessions or less, had "scorned delights and lived laborious days" in order to qualify himself to treat diseases according to the then current knowledge. Our own founder who, "while others slept, was climbing upwards in the night," had no more than a few weeks education—or what passed as such—in a veterinary college. From a training which, in 1844, was anything or nothing, the curriculum has gradually lengthened to a minimum of four years. Many are of opinion that a further increase is inevitable.

The lengthening of the curriculum has arisen quite naturally out of an expansion of the scientific veterinary horizon. The fact has from time to time been forced upon the authorities that, in order to produce practitioners fitted to fulfil adequately their duty to the public and the State, a longer, and yet longer time of preparation was necessary.

In spite of its increased length, the curriculum has not been rendered lighter. The same amount of work has not been spread over a longer time. On the contrary, the old subjects are now considered more fully and new subjects have been added. In the days of the two-session curriculum, pathology was scarcely in existence, and bacteriology—that science which has cleared up so many medical problems and has revolutionised surgery—was unborn. Protozoology is the progeny of yesterday, and some special lines of study are only to-day being contemplated. Hence it comes to pass that the four-year curriculum, introduced as recently as 1895, is already overburdened. How relief will ultimately be obtained remains to be seen, but there is just a possibility that the preliminary sciences—chemistry, physics, botany and zoology—will have to be taken in secondary schools before admission to a veterinary college. If this arrangement is ever affected, it will not be because the preliminary sciences are held of little value. Rather the opposite. They are so valuable as giving a scientific training and as cultivating a scientific mood that to remove them from a crowded curriculum would allow of their proper and desirable expansion.

Concurrently with the increase in the time taken to prepare the veterinary graduate, a change has taken place in the manner of the preparation. Time was, and that not very long ago, when all the equipment deemed necessary for the proper instruction of the student was a lecture room, a black-board, and a piece of chalk. To make the picture more truthful, it must be added that in some subjects there was a certain amount of practical work, and that towards the end of the student's career

he was expected to "see cases." But this was merely an extension of the "chalk and black-board" method. Except with the most acute and keenest student, the cases were merely looked at through the teacher's eyes. In short, the main duty of the student was to use his ears and his memory.

Though tradition dies hard, and the psychology of the student is such that he likes, sometimes even prefers, spoon-feeding, teachers have now so framed their courses that the student must do and see for himself. We are all familiar with the danger which attached itself to the old method of teaching—the danger of suppressing two very important and valuable attributes of youth—natural inquisitiveness and the pleasure of using the hands. The mere recital of a number of facts will never result in the education of the listener. The student must be put in the way of discovering his facts for himself. He must use all his senses, and, certainly not least in importance, he must use his hands. His hand serves a two-fold purpose. By it he will have to perform delicate manipulations and operations. And in it he has a sense which cannot be too highly cultivated—the sense of touch. It would be easily possible to speak at some length on the value of the sense of touch to the human and veterinary surgeon. It must here suffice to insist that the student is not doing his duty to himself if he does not avail himself of every opportunity to train himself to "think through his fingers," as it has been finely expressed.

The cultivation of every avenue of the mind naturally means an immense amount of practical work. No class, now-a-days, confines its labour to the hearing of lectures. Work in the laboratory and the clinique is imperative. The more this can be extended, and the less time given to the didactic lecture, the better will be the result. I am not one of those who see no value in the systematic lecture. The human voice is more living than the printed page, and problems can be more easily explained in the lecture-room than between the covers of a book. But it is recognised that the lecture is but one of the instruments in the hands of the teacher—and not the most valuable at that. "You do not educate a man by telling him what he knew not, but by making him what he was not." We want to avoid "ignorance in stilts, his cap well lined with logic not his own." What a student is taught is really of less importance than how he is taught it.

Without labouring the point unduly, it may be said that the main object of a teaching institution such as this is to train the student that he may be able to teach himself. Manipulative dexterity, the ability to observe minute differences, the faculty of reasoning, are all more important than the accumulation in the mind of a multitude of ill-digested facts. While remembering that we exist for the purpose of training the future veterinary surgeon, we do not forget that we are responsible for his education—the drawing forth of his faculties. We do not forget that, to do our duty, we must furnish him with such knowledge as will be of service to him when he goes forth into the world armed with his diploma. But we remember also that the imparting of "applied knowledge," without a leaven of that, the application of which is not apparent, leads to formalism, and formalism would be most stultifying in one whose success in life depends upon intellectual flexibility. We are also alive to the danger which exists of annihilating the healthy, and therefore highly desirable feeling of wonder and admiration. Care must be exercised also to preserve the power of imagination and lead it along fruitful lines. It is some years since a profound thinker emphasised the value of imagination in science.

Of all faculties, that of reasoning must be cultivated to the utmost. In a professional man the ability to accumulate facts without the ability to use them, is of

little value. Professor Huxley once divided scientists into the hod-men who accumulate facts, and the builder who uses them. In a profession it is only the user who is successful. Unfortunately, it is not easy for the embryo veterinary surgeon to collect his facts in the first place. When I say "his facts," I mean the facts which matter. It is not particularly difficult to note facts of a kind, but it is difficult to winnow the wheat from the chaff. We all know how easy it is to obtain the account of, say, a street accident from a by-stander. And we all know that the accounts of several by-standers will differ severally and individually. In most accounts the facts that matter are overlaid by a thick accumulation of irrelevant material. It is still more difficult for the student to correlate facts and reason from them. Nevertheless, both the faculty to gather, and the faculty to use must be present if success is to wait upon endeavour. The teacher of the student will first train the mental eye to see. So will knowledge of facts be attained. But "knowledge comes, but wisdom lingers," and the teacher is faced with the more difficult task of getting his pupil to arrive at a reasoned conclusion regarding observed facts. The mental, as well as the physical, vision must be made clear and penetrating, and this is often not easy of accomplishment.

The problem which confronts the teacher is, how is all this to be accomplished in classes, the members of which vary widely in natural and cultivated ability. As Prof. Thring has put it, pithily and unflatteringly: "All are to be taught. And knowledge is infinite. And life is short. And average brains are weak. How can this be dealt with?" The teacher is constantly being brought up short by variations in the limitation of the human understanding.

If aims and ideals as just outlined are right, it naturally follows that what was deemed sufficient accommodation and equipment in the past, would be considered lamentably inadequate to-day. This is brought home to us very forcibly by newspaper and other accounts of the immense sums of money which have been expended on medical and other schools during the past few years—an expenditure having its origin in the conviction that educational institutions fail in a public duty, and consequently fail to justify their existence, unless they fall in line with modern views and produce practitioners properly furnished in accordance with present-day standards. Nay, more, the schools have to look to the requirements of the future as well as the present, for the student of to-day will be the practitioner of to-morrow, and he must be mentally equipped to utilise not only the knowledge which is current to-day, but also the discoveries which to-morrow will bring forth.

It follows also that large classes, such as were formerly common, have had to give place to classes containing a number no greater than will allow the teacher to devote attention to each individual. A large practical class without adequate supervision means that some members at least will waste time, not from idleness, but because they cannot get the advice and assistance of the teacher when difficulties arise. It is obvious, I think, that the teaching staff of a modern professional school must be larger than was formerly considered necessary. The time is certainly past when one man could undertake to teach—save the mark—several different subjects.

One wishes it were possible to retain our most promising graduates for a time after they have obtained their diploma, by offering them teaching and research fellowships. To have, say, a session's experience as demonstrators and investigators would form a very valuable piece of post-graduate training. I sometimes think we should have at least one fellowship of this kind attached to each lectureship.

This reminds me that there is yet one more direction where lies a function and duty of the modern veterinary

school. Formerly, graduates on leaving College had little option but to become general practitioners. This is not so now-a-days. The majority certainly enter general practice, but a considerable and growing proportion enter one or other of the public services. All graduates receive the same general training as students. It is clear, therefore, that those who wish to specialise require further and special training. Hence has arisen a demand for post-graduate courses, which were unthought of less than twenty years ago. So important to the State has become the work of the specialist that a Departmental Committee has recommended the granting of financial assistance to those prepared to undergo post-graduate instruction with a view to entering one or other of the public veterinary services. The recommendation has not, as yet, been put into effect, but the "sweet reasonableness" of the proposal will surely be sufficient to ensure its consummation.

SOUTHERN COUNTIES VETERINARY SOCIETY.

The autumn meeting was held at the Old Ship Hotel, Brighton, on Thursday, September 25th, and was well attended. Invitations had been sent to the various veterinary inspectors in the counties covered by the Society, and prior to the meeting both members and visitors were entertained by the President, Mr. G. H. Livesey, to luncheon, at the Old Ship Assembly Rooms. Mr. H. A. MacCormack, the Hon. Sec. of the Central Veterinary Society, and Mr. Theo. C. Toope, the Hon. Sec. of the South Eastern Veterinary Association immediately supported Mr. Livesey at the luncheon, and the others who signed the attendance book at the subsequent meeting were Messrs. J. T. Angwin, Arundel; A. H. Archer, C. W. W. Brown, Southsea; E. Whitley Baker, Wimborne; Gerald W. Bloxsome, W. K. Stuart, Hove; Walter Burt, Brighton; Chas. J. Callow, Burgess Hill; W. A. DellaGana, Southampton; F. G. Samson, Mitcham; H. Smith, Worthing; and H. Whicher, Bexhill-on-Sea, members.

Visitors: Messrs. W. H. Brown, London; A. C. Burton, Battle; Percival Carter, Worthing; E. W. Morris, Uckfield; J. W. Pritchard, Brighton; and J. H. Ripley, Hurst Green.

On the proposition of Mr. Angwin, seconded by Mr. Samson, the minutes of the last meeting as published in *The Veterinary Record* were taken as read and confirmed.

Correspondence. Letters and telegrams of regret at inability to be present were announced from Col. F. Duck, Major F. Smith, Profs. Hobday, G. H. Wooldridge, and Messrs. R. Barron, H. Bradbury, R. Burt, J. V. Blake, Clement Baxter, James Crowhurst, J. A. B. Cocksedge, W. Caudwell, W. Coveney, J. B. Dier, R. Dawtrey, H. Edie, C. A. Good, C. Hedworth Gollidge, E. R. Harding, H. Jarvis, H. H. Jeffries, Hy. Gray, W. Hunting, Chas. F. Hulford, E. R. Harding, W. Irish, H. Leeney, G. H. Lockwood, E. Langford, J. A. Lipscomb, H. A. MacCormack, J. W. MacIntosh, G. P. Male, J. C. Munby, F. Maynard, F. Marks, Chas. W. Marshall, J. B. Martin (Rochester) Geo. Parr, C. Pack, W. E. Petty, C. Peirce (London), R. H. Pinching, A. E. Roberts (Bournemouth), C. Roberts (Tunbridge Wells), H. Redford, S. H. Slocock, C. H. Spurgeon, W. Smithers, Wm. Shipley, J. W. Shepherd, P. J. Simpson, R. A. Thrale, Hy. Taylor, J. A. Todd (West Kirby), G. F. Vincent, J. E. Wallis, D. Wyllie, F. T. Walder, J. Stewart Wood, A. C. Wild, Reg. F. Wall, and F. J. Thornton.

It transpired that the absence of Mr. Harding, of Salisbury, and Mr. Crowhurst, of Canterbury, was due

to the bereavements they have just sustained by the death of their respective wives, while Mr. Redford wrote that he had not yet quite recovered from the effects of a nasty accident which he unfortunately met with at the end of July.

Mr. E. WHITLEY BAKER proposed that suitable letters be written to each of the gentlemen mentioned conveying the sympathy of the Society. No one felt more sorry than he did to hear of the sad loss which had befallen Mr. Harding. He only heard from him the other day, and he then had no idea that Mrs. Harding was even ill. He would also like to suggest that a similar communication should be sent to their old friend Mr. Hunting, whom they would be sorry to hear had been unable to do anything for the last two or three months owing to an attack of otitis. He thought it was hardly necessary for him to say how sorry they all were to hear of Mr. Hunting's illness, and that they hoped he would have a speedy recovery. He proposed that suitable letters be sent to all four of these gentlemen.

Mr. ARCHER seconded, and the meeting unanimously signified its assent.

A letter was read from Mr. Chas. Roberts, of Tunbridge Wells, acknowledging the Society's resolution of condolence and sympathy with himself and the other members of the family on the death of his father, the late Mr. R. Roberts. His mother and the other members of the family wished him to express their very sincere appreciation and to say how much they had valued all the kindness which had been shown to them.

New Members. The election of Capt. OLIVER, A.V.C., who had been proposed for membership by Mr. Angwin, and seconded by Mr. Archer at the last meeting, was confirmed.

The following gentlemen were also nominated for election:—

Mr. SAM SMITH, of Horsham, proposed by Mr. Angwin seconded by Mr. Stuart.

Mr. PERCIVAL CARTER, of Worthing, proposed by the President, for Mr. Todd, seconded by Mr. H. Smith.

Mr. E. W. MORRIS, of Uckfield, proposed by Mr. W. Burt, seconded by Mr. Stuart.

Resignation of the Hon. Secretary, Mr. J. Aler. Todd.—The resignation was conveyed in a letter which Mr. Todd had written to the President from West Kirby, under the date of September 24th. Mr. Todd wrote:—"I take this step with great reluctance, but you will agree that having removed from Sussex it is impossible for me to continue. My 9½ years as an official have been years of pleasure to me, and I trust of some slight use to the S.C.V.S." Mr. Todd added that he wished publicly to acknowledge the ready help and assistance he had at all times received from their worthy treasurer, Mr. Baker, and from his own "second in command" behind the scenes, Mr. Aylott.

The PRESIDENT remarked that he was sure they would all agree this was a very sad one for them to receive. Mr. Todd had been a most excellent Secretary to the Society, and a good friend to all their members. Among the Secretaries of the different Societies throughout the country he thought there must be very few who could lay claim to the same popularity as their friend Mr. Todd could. (Hear, hear.) Now that Mr. Todd had removed from Worthing to West Kirby he could not possibly be expected to continue to discharge the duties he had so ably carried out for so many years. He would, therefore, like to move from the chair that the resignation be received with their very deepest regret, and that a letter be sent to Mr. Todd to this effect, and also wishing him, on behalf of all their members, every success in his new practice.

Mr. BLOXSOME seconded this.

Mr. THEO. C. TOOPE, as a visitor, desired to add a few words to what the President had said, and also to

express the great regret which he personally felt at Mr. Todd's resignation of the hon. secretaryship of that Society. As hon. secretary of a neighbouring Society, he could say that he had always received the greatest courtesy and consideration from Mr. Todd, and not only that, but Mr. Todd had also been of very great assistance to him in the inquiries he had been making with regard to the fees paid to veterinary inspectors, and other matters. He felt that they had lost a most energetic and capable official in Mr. Todd, and he heartily joined in their wishes for his future success. (Applause.)

Mr. W. K. STUART felt sure that the President had only expressed the feeling of every member of their Society in what he had said. They all knew that they had lost not only a dear old comrade, but a Secretary whose place they would have great difficulty in filling. Mr. Todd was certainly one of the keenest men who ever took on the office. When he first accepted the position he believed the members were very few. He only spoke from memory, but he believed the membership of the Society then was less than forty.

Mr. E. WHITLEY BAKER: Twenty-five.

Mr. STUART: Twenty-five, and he has now brought it up to nearly eighty, which I think speaks for itself. Mr. Todd not only did the work willingly, but he did it well, and he really thought the thanks of every veterinary surgeon in England, as well as those of their own Society, were due to him for what he had done. Personally, he thanked Mr. Todd most heartily for all that he had done. (Applause.)

Mr. ANGWIN, as a neighbour and very great friend, wished cordially to endorse all that had been said as to Mr. Todd's services to the Society. They greatly regretted that he was compelled to leave them, but at the same time he was sure it would be the wish of them all to send him a very hearty vote of thanks for the able manner in which he had conducted the business of the secretaryship of their Society, and also their best wishes for his future success. (Applause.)

Mr. SMITH also desired to endorse all that had been said. Having lived next door to him, almost, for the last fourteen years, he was particularly sorry to lose him. (Applause.)

Mr. E. WHITLEY BAKER remarked that he did not want to take up their time by repeating what other members had said, but having been associated with Mr. Todd in his official capacity as hon. treasurer, he could assure them that it was a very great grief to him to know that he was severing his connection with the Society. Not only had he carried out his duties efficiently, but he had also done what every secretary did not always do—he had carried them out in the most pleasant manner.

The PRESIDENT, in putting the resolution to the meeting, said he should like to add that he had known Mr. Todd ever since he came down to Brighton and joined the Society, and that during the whole of that time they had been more or less neighbours, and their intercourse had always been of the most friendly nature. Personally, he was very sorry indeed to lose him, not only as a neighbouring practitioner, but also as an ever and very welcome friend. (Applause.)

The proposition was then unanimously agreed to.

Mr. E. WHITLEY BAKER mentioned that several of the members were desirous that Mr. Todd should not be allowed to officially sever his connection with the Society without their showing their appreciation of his services in a tangible manner, and a sum of £17 had been subscribed or promised towards a testimonial to him. He did not know the views of the other members as to the form this presentation should take, but his idea was that they should send a cheque to Mr. Todd, and that they should supplement this with an illuminated address from the Society containing the names of the subscribers.

The general feeling of the meeting was in favour of this course being adopted.

Election of Hon. Sec.—The names of Mr. Walter Burt, Mr. Gerald Bloxsome, Mr. Della Gana, and Mr. A. H. Archer were in turn proposed, but three of these gentlemen declined, and Mr. Archer, who had been proposed by Mr. Samson, and seconded by Mr. Baker, was then unanimously elected Hon. Secretary.

Mr. ARCHER, in accepting the office, remarked that he could not hope or expect to fill the position so efficiently, or with so much satisfaction, as his predecessor Mr. Todd, but he would do his best, and if they were not satisfied with him at the end of the year they could easily turn him out and appoint someone else.

The ordinary business of the meeting was temporarily suspended, and the President invited the members to join him in drinking success to the late Secretary, Mr. Todd, and good luck to his successor, Mr. Archer. (Applause.)

Mr. DELLA GANA thought there was another toast they ought to drink—the health of their President. (Applause.) He was sorry he had been unable to get there at the commencement of the luncheon, but he got there in time to sample their President's hospitality, and he could assure them, and he believed he spoke for Mr. Whitley Baker his travelling companion as well, that they had never enjoyed a repast better in their lives. He asked them to join him in toasting their President, Mr. Livesey, and might he be spared for many more years to enjoy health and happiness, and the esteem and regard of his fellow practitioners. (Applause.)

The PRESIDENT, in reply, said that he was very much obliged to them for the cordiality of their welcome. His only regret was that there were not more present, but that could not be helped. He hoped they would get through the rest of the business of their meeting without any difficulty, and that they would all come again to Brighton before long and spend a pleasant time in the Queen of Watering Places. (Applause.)

Proceedings were resumed, and on the proposition of Mr. Burt, seconded by Mr. Della Gana, it was decided to hold the next meeting in London, on the Wednesday in Cattle Show week, and to follow it up with a dinner at the Holborn Restaurant in the evening.

ROYAL SANITARY INSTITUTE CONGRESS.

Mr. ARCHER presented a report of the recent Sanitary Institute Congress at Exeter, to which he had been appointed delegate, and on the proposition of Mr. Della Gana, seconded by Mr. Angwin, instructions were given for its inclusion in the report of the meeting.

REPORT OF DELEGATE.

Gentlemen,—In making this report of the 28th Annual Congress of the Royal Sanitary Institute in July last, which as your delegate I had the honour of attending, I shall recount the incidents as they appear to me to interest, or apply to the medical profession generally and especially our own particular branch of it.

The usual thoughtful arrangements were made for those who attended the Congress, and the welcome by the officials and inhabitants of Exeter and the neighbourhood was hearty and genuine, to which the numerous entertainments provided bore witness.

The inaugural address by the Right Hon. Earl Fortescue was a masterly oration, and the subject well thought out, but, as it dealt mainly with "rural housing" it was only of indirect interest to veterinary surgeons.

At the sectional meetings on Preventive Medicine and Sanitary Science, if those submitted at the Conference of Veterinary Inspectors (by-the-way why inspectors instead of surgeons) be excepted, there were only two or three that in any practical way affected veterinary surgeons, in fact, it occurred to me that there was a great lack of appreciation of the immense amount

of influence the lower animals have on the lives and health of human beings. The indifference or ignorance displayed, shows the need for educating both human medical practitioners and the public in these matters; one important way of doing this being by making ourselves seen and heard at these congresses and similar meetings. There was an excellent attendance at the Veterinary Inspectors' Conference which took place on the Wednesday, the President, Prof. Penberthy, gave an exemplary and interesting address, this being followed by thoroughly practical papers by Mr. Ascott and Mr. Stableforth, the former treating with the "Milk and Dairies Bill," the latter with "Tuberculosis in Cows," each of these eliciting some discussion which would doubtless have been considerably prolonged had more time been at our disposal, but as this was decidedly limited the speakers were necessarily obliged to keep strictly to the title-matter of the paper under discussion in each instance, and as the first mentioned paper was referring to a condition of affairs which, in its original original composition, is never likely to be put into practical compulsory working form; the discussion on this was necessarily of a somewhat vague character, while the subject of "Tuberculosis in Cows" in the narrow sense in which it had at that Conference to be dealt with, would have been much more suited to a meeting of medical men exclusively, than to a meeting composed of members of other branches of sanitary science, and in its turn suffered in consequence.

The paper on Public Abattoirs was well received and obtained the support of practically the whole of those present, and thereby was accorded the distinction it justly merited.

By, to me, some inexplicable circumstance, only the "abstract" of my own paper entitled "Transmission of Diseases of Animals to Man" was printed, consequently no one attending the meeting knew the details of the subjects contained in it, so that it could only be discussed in a very cursory and superficial way, and to but very little purpose, however, this paper was not singular in receiving this treatment, for at least to one other the same attention was accorded.

Reference to the tuberculosis question was a prominent feature, in the sectional meetings other than that of the veterinary inspectors, and it seemed to me that one could not fail to be impressed with the idea that, speaking generally, evidently the human medical practitioner intends to try to dominate the veterinary surgeon in administering the "Milk and Dairies Bill" when it becomes law, both in the matter of professional official position, and also in the important, if more prosaic, matter of remuneration; for, although some few speakers, notably Dr. Hamilton, Hertfordshire, expressed hopes, and even convictions, that human and veterinary practitioners would work smoothly and amicably together, yet even these conciliatory gentlemen made no mention of being prepared to share the "fees of office" equally with the veterinary surgeons, and as it is not to be supposed that Local Authorities will pay two fees for one job, unless divided equally, one must be bigger than the other. Which is to get the larger share? But after all, has not the (human) medical practitioner some amount of justice on his side, and a good excuse to plead his right to the attitude he takes up in connection with this matter, inasmuch as some of the veterinary inspectors under the Tuberculosis Order are untrained and unqualified men, and it cannot be right to expect qualified medical practitioners to work with, and on the same terms as these?

I mention this because this was about the greatest obstacle I had to overcome in impressing Mr. John Burns with the unfairness to members of the R.C.V.S., in the working of the Tuberculosis Order and the "Milk and Dairies Bill," supported as it is by the action of the

Council of the R.V.C., *vide* the Veterinary Surgeons Amendment Bill.

The Association of Veterinary Inspectors has, rightly, decided to ignore Registered Practitioners and other unqualified inspectors, by refusing them admission to the Association, and I am curious to learn in what light our foreign visitors to the International Congress will regard the *levelling-down* of the veterinary medical profession in this country, whether they will welcome and meet on equal social and professional terms these fortunate individuals who, by an uncostly and unlaborious process, obtain the "posts of honour" (?) in our profession.

Before closing I wish to compliment and thank Mr. Dixon, of Leeds, for the effective way in which he championed the cause of the veterinary profession throughout the whole Congress, for I assure you that any good that this profession may derive from this Congress will in no small measure be due to the tact, energy, and perseverance of our recording Secretary, Mr. Dixon.

Mr. BURT thought they also owed a debt of gratitude to Mr. Archer for attending the Congress as their delegate and preparing the report, and with the President's permission he desired to propose that a hearty vote of thanks be accorded him for it.

Mr. STUART seconded, and the meeting agreed.

Mr. ARCHER: Thank you, gentlemen, very much for your vote of thanks. I should like to add that I have only included in this report what was, in my opinion, of interest to and likely to benefit the members of the profession.

The PRESIDENT said that, with the approval of the meeting, they would next deal with the matter for which the veterinary inspectors had been specially invited, and in connection with this he would like to read them an extract from a letter which had been received from Mr. Baxter, of Christchurch, after which he would ask Mr. Toope to open the discussion. Mr. Baxter, in expressing his regret that he could not accept the invitation to attend that day wrote that "as a veterinary inspector for a section of Hants. he was satisfied in the meantime with the treatment he got at their hands. He had had experience of County Councils in Scotland and found them "much nearer the bone" than the County Council of Hants." Mr. Baxter further expressed the opinion that the fees to swine fever inspectors should be cut down, as they seemed to know little about the diagnosis of the disease.

Mr. THEO. C. TOOPE, in complying with the President's invitation to open the discussion, observed that he felt more or less in the position of a missionary preaching the gospel of unity—(laughter)—but at all events he was not addressing the heathen, and he had no doubt that his remarks would be received in the spirit he intended them to be. He had come there that day for the purpose, he hoped, of putting some of them in the way of obtaining better fees. That had been his aim for some little time past, and he thought he could say with some little success so far as his own county of Kent and some others were concerned. As to the necessity for union among themselves, he thought there could be no two opinions, and the only question was how they could best produce this unity. He held that it could best be brought about through the medium of the existing Societies, and his own proposal was that each Society in the area covered by the Southern Branch of the National should form a veterinary inspectors section, and that the veterinary inspectors section should, whenever necessary, deal with matters affecting themselves at, or prior to, the general meetings of the Society. If the particular matter requiring attention was of general interest to the other members of the profession, as well as to those who were inspectors—and

there were a large number of questions that were of interest to those of them who did not happen to be inspectors—it could be dealt with along with the other business of the meeting, but if the matter affected the veterinary inspectors only it could be dealt with by themselves prior to the ordinary meeting. They had already got this plan in operation in the South Eastern Society; the meetings of the veterinary inspectors section being called for the same day as the ordinary meetings of the Society, and what he wanted them to do that day was first of all to form a distinct veterinary inspectors Committee, consisting of one or more inspectors from each county or division of such and that that Committee should consider and deal with all matters affecting the veterinary inspectors. By adopting this plan any resolutions passed by the Veterinary Inspectors Committee could be passed on through the Branch Society to the National Society in the same way as the question of the fees had been passed on by his own Society. There was not the slightest difficulty in carrying out this plan. All that was necessary was to call the meeting of the veterinary inspectors half-an-hour or an hour earlier, and invite them to remain to the general meeting of the Society afterwards. This should have the effect of considerably augmenting their numbers also. The fees paid in many counties were admittedly bad. Some inspectors were satisfied with them—as the gentlemen whose letter they had just heard read. Some were easily satisfied, but were they satisfied with their existing fees? He had no hesitation in saying that the fees offered by some counties might satisfy a chimney sweep, but they certainly should not satisfy a professional man. He did not suggest for one moment that they should produce a scale of fees and attempt to force it upon the Authorities. If, however, they could produce a scale of fees that had met a general approval, and by means of deputations from the veterinary inspectors to the Authorities, they could satisfy the latter that the scale submitted was just and fair and had been accepted by other Authorities, they would be going a long way towards attaining their ends. With regard to the duties under the Act, he strongly advised every veterinary surgeon to claim his full duties, and not do as some had done, give away the microscopical work. If it were impossible for various reasons for the inspector to do this work himself, surely, instead of handing it over to others outside, he should hand it over to those members of their own profession who were able to do it. Why should they encourage analytical chemists to do this work for them when there were plenty of men in their own profession who could do it? At the last meeting of the South Eastern Society at Ashford this very matter cropped up on receipt of two letters from veterinary surgeons in Surrey, drawing attention to the fact that an analytical chemist in a certain town was advertising that he had time to do this work for veterinary inspectors. Again, if it were necessary that evidence should be given as to whether there were bacilli or not, surely it was to their interest that that evidence should come from a veterinary surgeon rather than from a chemist.

He had been struggling with the subject of the fees received from the insurance companies for some time now. As Mr. Morris would put it, he had focussed it to a coarse adjustment, and he was now bringing the finer adjustment to bear; and he thought that within the next few weeks the National Society would be in a position to put them in the way of obtaining better fees for their services in that direction.

Mr. WALTER BURT expressed himself as very much obliged to Mr. Toope for his remarks. He himself happened to be a veterinary inspector. He did not say that he was satisfied, but it appeared to him that the whole thing turned on this: that the members of the Society who were not veterinary inspectors, and whose

toes they often trod on, could not be expected to have much sympathy with those who were. Personally, he did not expect sympathy from his fellow practitioners, but it was no use blinding oneself to facts. They might say he was a cynic, but he had come to the conclusion that by far the larger proportion of their own profession were exactly the same as the larger proportion of mankind in general, and were always and necessarily on the look out for themselves; and they could not get away from the fact that there were many veterinary surgeons who objected very strongly to the veterinary inspector. He admitted it would be a very good thing if they could bring these men and the veterinary inspector together, but he was afraid that to ask for the assistance of other members who were not veterinary inspectors to improve the position of those who were, would be putting somewhat a strain on human nature. He was inclined to think that the veterinary inspectors must fight for themselves. There was also this to remember—that if they increased the fees sufficiently they would find the Authorities would be wanting to appoint whole time inspectors. If local authorities found they were paying say £400 a year in fees, they might decide that they could for the same expenditure obtain a splendid man who would devote his whole time to the work with probably much better results. The appointment of whole time men, too, would not be open to the same objection, probably, from the individual veterinary surgeon, because the latter did not object so much to the whole time official as he did to the fellow practitioner who came on to his preserves from a neighbouring district. He was rather lucky himself in the fact that they were all more or less friendly in his district, and he should consequently not mind going to any of his brother practitioners, but he could conceive it quite possible that if a man sent his slides to another practitioner it would not be long before the fact would leak out, and the other men would be in the running for the inspectorship. He quite agreed that it was desirable to keep this milk business in the hands of the veterinary profession, and he also agreed as to the desirability of co-ordination of veterinary inspectors, but he candidly confessed that he could not see what good a veterinary inspectors' branch was going to do the Society, or what good it was going to do the veterinary inspectors for that.

Mr. STUART remarked that he was not a veterinary inspector, and he did not intend to be, but he quite saw the force of Mr. Toope's arguments, and he also appreciated the force of what Mr. Burt had said. Mr. Burt, however, was in a somewhat unique position; he was in the midst of a lot of pals who always worked well together, and consequently he was probably much more favourably placed than many others were. He honestly thought that they ought to work together for one end, and that was the advancement of the interests of their profession. It was becoming more and more a question of union with every calling, and if they did not adopt the same principle he was very much afraid they would find they would be left in the end. He thought they ought to make up their minds to support the veterinary inspectors, and follow the advice given them by Mr. Toope.

Mr. ANGWIN had listened with considerable interest to Mr. Burt's remarks and also to the somewhat Utopian idea Mr. Toope had expounded to them; but Mr. Toope must remember that their Societies were generally small and that they wanted members and if their Society were going to uphold the inspectors, he thought they ought to be members of their own or some other Society. Their doors were open to all veterinary surgeons.

Mr. MORRIS did not think there was danger of their ever getting whole time inspectors appointed—for this reason. In East Sussex, to take his own district, there were sometimes several sales and markets

taking place on the same day. How could one man attend them all? He certainly thought, however, that they ought to get better fees for the work they had to do. In a case of anthrax, for instance, it often meant going fourteen miles for threepence a mile, and half a guinea for inspecting a carcass, and then coming back and getting nothing for the microscopical examination. It was also much the same with mange. He thought they ought to make a little more stand over this microscopical work. He quite agreed, too, with what had been said about keeping the microscopical work in their own hands, and if they could not do it themselves they ought to be careful who they employed to do it for them. Then, again, with regard to their diagnosis in cases of anthrax, he thought more attention ought to be paid to it. Surely it would be better for the county to pay half-a-guinea for a microscopical examination and save the cost of the wood and coal required to burn a large carcass not affected. Personally, he thought that if that Society wanted to increase its membership it would do well to form this Veterinary Inspectors Branch.

Mr. DELLA GANA, as one who was not an inspector, remarked that he had been very much interested in the discussions they had had. They had heard a great deal said at different times about the incompetence of many of those who were acting as veterinary inspectors, but he should like to know why it was that such incompetent people got the appointments. (Laughter).

Mr. BURT, speaking as a veterinary inspector, I should say it is a matter of ill luck. (Laughter).

Mr. PRITCHARD, on being appealed to for his views, said that he could only tell them what had been done in West Sussex. When the Order was issued they held a meeting in London, and they there decided to ask to be allowed to do the work for which they ought to be qualified. Then the seven inspectors in West Sussex had another meeting at Horsham, at which it was decided to forward the scale of fees suggested by the National to the County Council, with a request that that scale might be adopted for West Sussex. The Clerk to the Council afterwards wrote acknowledging the receipt of this, and stating that the matter was under discussion by the Committee, but nothing more had been heard of it since. He mentioned this to show that in West Sussex, at all events, they were unanimous, and that they had not lost any time.

Mr. BURT remarked that the inspectors in East Sussex also had a meeting at Lewes, and a deputation appeared before the County Council. There, again, the matter was under discussion; but that was as far as it had got, and in all probability it would go on being discussed.

Mr. H. SMITH mentioned that when he approached the Clerk to the County Council for West Sussex, with reference to sending in his account he was told he must not send in his bill until they had decided what fees they were going to pay.

Mr. RIPLEY thought the County Council had been very fair up till now.

Mr. STUART remarked that not being an inspector himself, perhaps the President would oblige him by telling how these appointments were made.

The PRESIDENT: I am afraid I don't know anything about that.

Mr. MORRIS said he believed the procedure was this:—First they had to get a recommendation from the sub-committee for their own particular district, and that the local sub-committee recommended one to the executive committee, who made the appointment.

The PRESIDENT, interrupting, observed that he was afraid the discussion was getting a little wide of the object of that meeting. They had asked the veterinary inspectors to meet there for a definite and specific

purpose, namely, organising their forces, but at the present moment instead of organising they seemed to be simply criticising. It seemed to him that one of two courses was open to them. Either the veterinary inspectors might like to organise themselves, or the Southern Counties Society could decide to form a veterinary inspectors branch as suggested by Mr. Toope.

Mr. STUART, to bring the discussion to a definite issue, proposed that steps be taken to form a Veterinary Inspectors Section with their own Committee and Hon. Secretary.

Mr. CALLOW seconded this, and on being put to the vote it was agreed to *nem. con.*

Mr. TOOPE remarked that the next course would be to write to the veterinary inspectors in each of the counties covered by the Society asking them to suggest names for the Committee from their own particular county. The success of the South Eastern Society had been largely due, in his opinion, to the efforts they had made in this direction, and he must say he thought they had come to a wise decision. Veterinary inspectors were too wide apart to be able to form an association of their own, and if they made the Society the centre for them they would find they would soon become members of the Society.

The PRESIDENT: I should like to ask you, Mr. Toope, whether you think notices should be sent only to those inspectors who are members of our Society or not.

Mr. TOOPE: I should say invite every one in the first instance, but the members of the Committee which you will appoint, I take it, at your next meeting, should be members of your Society.

Mr. ANGWIN handed round for the inspection of the meeting two interesting X-ray photographs. One was an X-ray of a split pastern, and the other was a photograph of a cat which had been shot climbing a tree and in which the pellet had entered above the pelvis and had travelled down the leg to the centre of the femur.

He also mentioned that he had had an interesting case recently of a horse being poisoned from eating tamarisk hedge. He had always been under the impression that tamarisk was not poisonous, but there were several kinds of tamarisk, and in this instance the animal was clearly poisoned by eating it.

Mr. TOOPE remarked that the photographs were both of them exceedingly good. One could deal with a small animal fairly easily, but a larger one presented a considerable amount of difficulty. It was very difficult to keep them still for one thing, another difficulty was that the tissues were so thick that one needed a very long exposure before one could get a satisfactory negative, and very often when they got the negative they could not get a decent print from it. It was very interesting work, and he thought more use might be made of it in diagnosing difficult cases of fracture.

Mr. ANGWIN: If you want to take an X-ray of a horse it is not a bit of good doing it with small power. You want a coil that will throw at least a twelve inch spark; and the next thing is that you must be in the dark. It is, as Mr. Toope says, very interesting work, but very expensive.

Mr. CALLOW proposed a hearty vote of thanks to the President for his hospitality that day, and this was seconded by Mr. Smith, and carried by acclamation.

A similar compliment, on the proposition of Mr. Archer, seconded by Mr. Callow, was also paid to Mr. Angwin for bringing the X-ray specimens. This terminated the proceedings.

A. H. ARCHER, Hon. Sec.

Registration of Rural Slaughterhouses.

At last monthly meeting of the Rural Council, the Deputy Clerk said a matter adjourned from the previous meeting for the attendance of the Medical Officer, was a communication from the Local Government Board with regard to slaughterhouses in the Leominster rural district.

Dr. Jones thereupon made a statement, in the course of which he said there were no regulations for slaughterhouses in the rural district. Slaughterhouses were regulated under an old Act of Parliament which only applied to towns, and the only way to get them regulated in rural districts was to get urban powers for the purpose, which were readily granted. An inquiry would be held by the Local Government Board at which all the butchers of the district would have an opportunity of attending. The Ledbury rural district had obtained those powers, and the butchers of that district preferred to have the slaughterhouses registered, because if those places were not registered anybody could slaughter anywhere. Slaughtering should be carried out under proper conditions. There were four slaughterhouses in the Leominster rural district, and they were now under practically no supervision. It did not mean that a man who killed a solitary sheep or pig occasionally would have to have his premises registered, but those who habitually used slaughterhouses.

Mr. Smith gave notice that he would move at the next meeting that they apply for urban powers for the purpose of regulating slaughterhouses.

After a prolonged discussion, the Chairman said he thought slaughterhouses should be registered in the interests of the health of the public. If a smallholder

had an animal that was not up to the mark he might kill it for human consumption, and to prevent that he ought to be registered also.

A serious report was made to Battle Rural District Council by the Sanitary Inspector. He stated that on receiving a telegram from the Hastings Public Health Department, with reference to a diseased pig sent to Hastings from a parish in the Battle rural district, he examined the carcass, which was ordered by the justices of the peace to be destroyed. The report further stated that five pigs were taken from their owner to a slaughterhouse in the Battle district, and were there killed. The pigs were afterwards taken to a Hastings butcher's shop, and the butcher noticing one was diseased reported the matter to the Hastings authorities. As there was not sufficient evidence of guilty knowledge Mr. Jenner did not advise the Council to prosecute in the case, but recommended that the interested parties be cautioned. The case might be taken as more evidence that slaughterhouse bye-laws were urgently required.—*Meat Trades' Journal*.

Prosecution under the Tuberculosis Order

Before the Marlborough county magistrates on Saturday, the 13th inst. The defendant was Mr. Kenneth Alexander MacAndrew, farmer, of Wexcombe Manor, who was charged by Supt. Mackie, having failed to notify the police, in accordance with the requirements of the Tuberculosis Order of 1913, that he had in his possession, on August 25th, a cow which appeared to be suffering from tuberculosis, with emaciation.

Supt. Mackie stated that on September 1st he saw the cow slaughtered. The animal was examined by Mr. J. McKerlie, M.R.C.V.S., whose certificate he produced, showed that it was suffering from advanced tuberculosis, with emaciation. Supt. Mackie added that he afterwards saw Mr. MacAndrew, who admitted that he was responsible for it being sent to Swindon market. On being informed that he ought to have reported the animal, defendant said he had no knowledge of the Tuberculosis Order, nor had he seen any copy of it posted up in the neighbourhood.

In cross-examination by defendant, Supt. Mackie said he examined two cows, a roan and a red, a few days before, in the presence of Mr. McKerlie. It was a red cow which was killed. The roan appeared to be in the worse condition. When tested for tuberculosis, the red cow reacted, but the roan did not. Reaction did not necessarily determine the existence or otherwise of tuberculosis. The roan cow was so bad that he hardly considered it necessary to test it.

Mr. J. McKerlie, veterinary surgeon, of Hungerford, called for the defence, said he tested the two cows, one of which responded to the tuberculin test, and the other did not. That which responded was killed by order of the Superintendent of Police. The other was subsequently killed, and was found to be suffering from abscesses in the liver. The latter cow was much worse in outward appearance than the other. There was nothing in the outward appearance of the red cow to show that it was tuberculous beyond being poor. The roan cow was more emaciated, and, therefore, more suspicious in appearance. Sometimes cattle in good condition—almost fat—were found to be suffering from tuberculosis.

Defendant was sworn, and stated that the cows referred to were old, and rather poor, but there was nothing in their appearance to cause him to be suspicious of tuberculosis, otherwise he would have called in the services of Mr. McKerlie. He had never read anything about the Tuberculosis Order, although he was aware that he was expected to know the provisions of the law.

Mr. McKerlie, recalled by the Bench, stated that, beyond being poor, there was nothing in the appearance of the red cow to cause an ordinary individual to suspect that it was suffering from tuberculosis. There were so many conditions leading to emaciation in cows that farmers did not as a rule consult a veterinary surgeon when animals were poor.

The Bench intimated that they had given careful consideration to the case, which was the first they had had before them under the Tuberculosis Order, and they had decided to dismiss it.—*North Wilts Herald*.

GLASGOW VETERINARY COLLEGE.

The new session of this College opened on Wednesday, Oct. 1st, after practically the reconstruction of the buildings. The College now consists of a splendid suite of rooms and halls, containing all the requisites for veterinary purposes. The College is recognised and subsidised by the Government through the Board of Agriculture for Scotland, as a central institution, and is under the control of a representative Board of Governors appointed by the various City and County Councils. Under Principal M'Call and his large staff of lecturers, the College is increasing in popularity every year, and judging by the number of pupils who submitted themselves for enrolment on the opening day, the College is likely to serve its purpose in the future more efficiently than ever.—*The Scottish Farmer*.

SOCIETY OF VETERINARY OFFICERS OF HEALTH.

The Sixth Annual Meeting was held on Friday, 3rd inst., in the County Buildings, Hamilton, and was attended by delegates representative of all parts of the United Kingdom. The President of the Society, Mr. Hugh Begg, F.R.C.V.S., Veterinary Inspector for the County of Lanark, occupied the chair. He extended to the delegates a hearty welcome, and in his presidential address dealt with the recent Tuberculosis Order. He said, however thankful they might be for the present limited Order, considering the lukewarm state of the public mind, it was evident to all—those who framed it, and those who administered it, as well as the stockowners—that until the Order was amplified it could not be considered a measure of eradication even in a remote sense.

It was agreed to hold next year's meeting at Kilmar-nock, and Mr. T. A. Douglas of that town was appointed

president for the ensuing year. The Secretary, Mr. A. M. Trotter, Glasgow, was re-elected.

Thereafter Mr. Thomas Munro, County Clerk of Lanarkshire, submitted a paper on "The Tuberculosis Order of 1913." A discussion on the paper followed, and was contributed to by Professor Dewar, Edinburgh; Mr. Parker, Newcastle; Mr. Lloyd, Sheffield; Mr. Robb, Glasgow; Mr. Dixon, Leeds; Dr. Erskine, Glasgow; Dr. Davies, Edinburgh; Councillor Bashford, Sheffield; Messrs. Storie, East Linton; Douglas, Kilmarnock; Brown, Invergordon; Anderson, Cupar-Fife; and Campbell, Berwick.

On the motion of Mr. Raynard, Perth, a vote of thanks was accorded Mr. Munro for his paper, and as a practical outcome of it and the subsequent discussion, the following resolution, moved by Mr. Lloyd, and seconded by Mr. Robb, was unanimously adopted:—"That the Board of Agriculture be urged to so widen the scope of the Tuberculosis Order of 1913 as to include cattle in it which can be demonstrated by microscopical examination of the discharges to be actively capable of spreading infection to other animals."

The delegates afterwards adjourned to the county laboratory, where Dr. J. Hume Patterson, county bacteriologist, gave a microscopical examination of milk for the detection of tubercle bacilli.

The company dined in the County Club, and thereafter took part in a drive to the High Parks and Cadzow Castle.—*The Scotsman*.

Cruelty Charge at Folkestone

On Saturday, Sept. 27, Alderman Vaughan in the chair, Charles Ramsden was summoned for working a horse in an unfit state, and John Harnett was summoned for causing the horse to be so worked.

Mr. J. W. Gambrill appeared at the instance of the Horse Owners' Association, and pleaded not guilty.

P.C. Whitehead said that the animal was very lame on both fore legs. Witness stopped defendant Ramsden and pointed this lameness out to him, and he said "it is a bit." Witness examined the horse and found the tendons much inflamed and the feet tender to the touch. Defendant said he had only driven the horse for a fortnight, and he had not pointed out the lameness to Mr. Harnett. Witness thought the horse was 20 years old, and he considered it to be an act of cruelty to work it in its condition. At 4 p.m. on the same day witness, with Inspector Bennett, R.S.P.C.A., saw the horse in the stable, and at 8.15 p.m. he saw Mr. Harnett, the defendant, at his house. Inspector Bennett asked him whether he had any explanation to make, and he replied, "I take full responsibility for my horses. I admit this one has gone a bit stiff for some time, but it went better yesterday than it has done for a long time. The horse was fresh shod yesterday. That is all I know."

Inspector Bennett, of the R.S.P.C.A., said that the animal was about 20 years old. It was extremely lame on the near fore leg. The tendons were very much inflamed, contracted and painful to the touch. The fetlock joint was deformed. The horse had also got ring-bone. The heels of both fore feet were tender to the touch. The animal was totally unfit for work. It would be an act of cruelty to work the horse in its existing state.

In answer to the Chairman, witness said the mare was destroyed on Monday afternoon in accordance with witness's suggestion.

Mr. T. C. Gillard, veterinary surgeon, said that he examined the horse on Sept. 15th. The animal was intensely lame in the near fore leg. The cause of the lameness was the chronic condition of the tendons and the deformity of the fetlock. The animal was too lame

to trot—witness merely had it walked up and down for purposes of examination. It was quite unfit for work, and must have been so for some time. The lameness was of several months' standing.

Ramsden said he had been employed by Mr. Harnett for a month. He started on his round at 9 a.m. on the day in question. The horse was not lame then. Witness returned after two hours, and the horse was not lame then. He started out again at 11.30, and he did not notice the horse to be lame then. The day previously he drove the horse past Inspector Bennett on two occasions. Witness had received no warning from the Inspector concerning the horse. He thought the lameness must have been caused by the horse slipping shortly before witness passed the constable.

Edward Wm. Harnett said his father had been ill since November, and witness had managed the business. He had always impressed on the stablemen never to take the horses out unless they were fit. On the morning in question, witness saw the horse start out at 9. She was then all right. She covered the round in the same time as usual.

Chas. Alfred Davies, stableman in the employ of Mr. Harnett, said that on the morning in question the horse did not appear to be lame.

Mr. H. B. Eve, veterinary surgeon, said he inspected the horse on Sept. 13th at the request of the Horse Owners' Association. The horse was absolutely dead lame on the near fore leg, the result of complete breakdown of the back sinews, caused perhaps by slipping on the road. He received instructions from Mr. Harnett to destroy the mare.

Cross-examined: In all probability the horse would start out "groggy." Witness did not think it came out legally sound, but it might have come out workably sound. There was a vast difference between the two terms.

The Magistrates retired to consider their decision. They dismissed the summons against John Harnett, on the grounds that he had not been connected with the business for some time. As the horse had been destroyed, the summons against Ramsden was dismissed, on payment of 13s. 6d. costs, and the veterinary surgeon's fee of £1 1s.

British Empire Trophy for Bacon at the Dairy Show.

The Council of the British Dairy Farmers' Association has decided to create a special class at the Dairy Show, to be held in the Royal Agricultural Hall, London, October 21st to 24th, 1913, inclusive, for bacon cured anywhere throughout the British Empire. There are at present a number of classes for bacon and hams at the British Dairy Show, but hitherto the exhibits in these have been confined to the United Kingdom. The Council of the British Dairy Farmers' Association have come to the conclusion that the time is opportune for the creation of the class referred to.

It is proposed that the class should be open to bacon curers in the United Kingdom, the British Colonies, British Protectorates, and the British Empire. The exhibits must consist of two sides of bacon smoked, and two sides of bacon pale dried. The weights admissible for this competition will be not less than 56lb per side, and not more than 68lb per side. The curing must be done in the Exhibitors' own premises, but the drying and smoking may be done in the United Kingdom, under a certificate from a duly accredited representative of the Governments concerned.

The trophy referred to will take the form of a cup, value fifteen guineas, as first prize; cup, value five guineas, second prize; and another, value two guineas

third prize, as well as other awards. It is proposed that the entry money for the class should be two guineas per exhibit.

The Secretary will be glad to give any further information.

FREDK. E. HARDCASTLE, Secretary.

British Dairy Farmers' Association.
12 Hanover Square, London, W.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Sept. 26.

Death occurred on Oct. 7th, from chronic Bright's disease, at the age of 66 years.

CORRESPONDENCE.

THE PANAMA CANAL AND SOUTH AMERICAN DISEASES.

Dear Sir,

In connection with the now approaching opening of the Panama Canal I am taking the liberty to warn, through your columns, veterinary surgeons and agriculturists of a new focus for the introduction of disease into the British Isles. In Chile and Peru is produced hay known as Alfalfa. It is a legume more or less the same as Lucerne, but yields three or four crops a year. The Peruvian differs from the Chilean in being longer in the stem, and the stem of the Chilean is hollow. In these countries one passes nine months of the year without rain, and the whole of the crops are watered from a series of canals which bring down the melting snow from the Andes. These canals are often used for the animals to drink from, and to carry away sewage, excrement, etc., which is deposited on the growing crops. So dry is the climate that the alfalfa is cut one day and made into tight trusses, or *fardos* the next. These *fardos* weigh about 90 kilos. (200 lb), and without grain of any kind will keep a hard-working horse for more than a week. My own saddle horses only get half a *fardo* each week allowed them, and they are quite good for forty kilometres a day, and my weight with saddle is 75 kilos., but these get several halts. This alfalfa I find to be the most nutritious and cheapest food I have encountered in all my professional career. It is grown in a country famous for its nitrates. The very soil is full of them, indeed so rich that the Chilean farmers rarely use any form of manure.

But this is quite a bye-question. The country of Chile in its agricultural zone, i.e. between Coquimbo in the North and Port Monte in the South, is very much infected with foot-and-mouth disease—the authorities of Santiago fine the owner £1 for every cow he sends to market which is detected—but against this disease remedial means are taken. The best I have found to the present is Chlorate of Potash, 60 grams in one half litre of water, repeating in ten days, and not treating the local eruptions. The disease here seems more benignant than in the Argentine, due, perhaps, to the more benignant climate.

Another disease very prevalent here is known as *mal de maeda*. This has been investigated this last year by my colleague, M. Blier, formerly of Lyons, bacteriologist, but as his report is not yet ready I can only tell you that the symptoms are almost exactly the same as described by Hayes (Vol. I.) of Redwater in South Africa; but Blier, in his experiments, has found a spirilla which he believes to be the cause. I will send you further details later.

Anthrax is the plague of the fat cattle breeders, but singularly enough I have not noticed it among the dairy cattle to any great extent. I myself got anthrax through a post-mortem on a horse, which died within two hours—I enclose you notes taken at the time, but they are very imperfect. The people here eat the flesh of dead animals, and as many as 20 or 30 in one village have died, but the authorities are very lax and try to shut the door after the horse has run away.

Another disease prevalent here is *Mal de Caderas*, and bearing in mind that so good a judge as Mr. Hickling, of the Hackney Society, has said the native Chilean pony is the best type of pony he has ever seen, it seems a pity to have to say this. My experience, clinically, of this disease

is that it is one of the most insidious and takes two forms, acute and chronic, but of this more anon.

My purpose is to warn, through your widely read journal, those interested in the feeding of stock and the elimination of disease, that as soon as the Panama Canal is open it is a new "open door." One ton of alfalfa can be landed in London for £6, and who knows how many diseases for make-weight.

WM. J. MOODY, F.R.C.V.S.

Santiago, Chile. Sept. 9th.

LAMENESS.

Sir,

I beg to thank the writers who criticised my note on the above subject. One writer, however, "Anti-Humbug," has rather misunderstood my remarks in a few instances, and a little explanation will probably show that we do not differ to a marked extent.

1. I am not "very sensitive of what the public think of, or care about, our diagnoses." Personally, this matter does not trouble me, but from a commercial aspect one has to pay attention to the views of the public, otherwise that very important book, the ledger, would suffer, and in these days of competition and motor traction, one is compelled to pander to the whims and caprices of clients. Probably if I were in the happy position of being independent of practice, or had laid by the nest egg, I should find no better form of amusement than telling clients just what my candid opinion was of themselves and of their animals. Probably, too, they would appreciate such opinions, when they were aware that I did not take the pains to retain their patronage or submit to their vagaries.

2. I did not intend my remarks to apply to the junior members of the profession. In my experience the "Sir Oracles" belong to the senior members, those "dressed in purple and fine linen," who, from their standing and reputation are able to assume the mantle of infallibility, and who, like the stoics of old, "never are in doubt, never suffer remorse, never change their minds, and never made a mistake."

It is the junior member who is conscious of committing errors—too conscious at times, when he has to compete with one of the type described by the poet as "most ignorant when he's most assured."

I do not agree that wisdom always comes with experience, for examples are not wanting to demonstrate that in mature age many men persuade themselves that they cannot make mistakes; the juniors, on the contrary, very soon find out the veracity of *Humanum est errare*.

3. With reference to navicular disease, I am quite aware that in the early stages a very careful examination of the navicular bone is necessary in order to detect the lesions. But I am also aware that many cases are diagnosed as navicular disease, the horses pass into other hands, and the after-history shows that they go sound. I am very sceptical as to the possibility of a horse affected with navicular disease being able to go sound for any length of time. No doubt it is easy to assert that the seat of lameness is in the navicular bone, but to prove it is quite another matter.

It would be interesting to ascertain the number of aged horses that on post-mortem examination would show perfectly normal navicular bones, i.e. on histological examination.

4. With reference to the remark "Whining is symptomatic of a peevish disposition," I may suggest that if all were satisfied with the present state of affairs and did not whine, or even bark and bite occasionally, progress would be slow or non-existent. It is well to enquire into existing views and methods, and to challenge their accuracy. It is of advantage to be sceptical, and not to blindly follow the dicta laid down by either authorities—text-books or successful practitioners. It is right and proper, although not always pleasant, to confess ignorance on many points, and to cast aside the veneer of pharissical superiority which is so often assumed.

Energies devoted to exposing the shams and sophistries that exist in the profession are by no means wasted. Nothing does more to purify the professional arena than to demonstrate to the public that men of supposed great

skill—the giants of their time, the great Moguls whose opinion is never questioned—can make mistakes quite as readily as the juniors, who, while possessing high ideals, are unable to conceal their errors. The latter often lack the Pecksniffian code of morals which, boldly practised, so often leads to commercial success, and noble reputations. —Yours, etc.,

E. WALLIS HOARE.

CAUSE AND PREVENTION OF "MILK FEVER."

Sir,

As I am interested in this subject and would like to give every man his due, irrespective of nationality, I should be much obliged if Mr. A. H. Archer could inform us, through the medium of your valuable journal, the cause of parturient apoplexy, the name of his authority who demonstrated that cause, and also of him who forestalled Herr Schmidt? I would also like him to give us the title of the papers of his authorities—the journals in which they are recorded, the pages and dates?

Until I read Mr. Archer's article in your last issue I was under the impression that it was acknowledged by the veterinary world that the cause of "milk fever" was not understood, and that the credit of introduction of the successful treatment of it belonged to our Danish *confrère*, Herr Schmidt, who deserved the thanks of the stockowners of the world for saving to agriculture many thousands of pounds sterling every year.

Is Mr. A. H. Archer unaware that professional and scientific men should know no nationality, in science or practice, and that each member should treat the other with that courtesy which is expected of all men of knowledge.

It should be remembered that Frenchmen were the first to establish modern veterinary schools and to disseminate scientific knowledge of the diseases of animals. Notwithstanding the mite we have added since, where should we be to-day without our brother "the foreigner" of whom Mr. Archer speaks rather cynically!

If Mr. Archer's ungenerous insinuation, that the credit of the treatment "accidentally stumbled" across by Herr Schmidt did not therefore belong to him, were correct, could not the same be said of Lister, considering that improvements of antiseptic and aseptic methods have displaced the carbolic spray, etc.?

Personally, I look upon Schmidt's method as the greatest discovery in practical veterinary medicine; it has reduced a relatively fatal disease to a relatively curable one.

In conclusion, Mr. Archer should remember that *nothing is accepted by the scientific minded until it is proved*; that discoveries are generally made by accident and by those who have the genius to observe fresh phenomena and interpret them in practice or in science.

JUSTITIA.

AIDS TO THE V.V.B. FUND.

Dear Sir,

I noticed the letter of Wm. T. D. B. in your last issue, and thank him for his suggestion.

As a matter of fact I have in my surgery a collecting box for our Fund, principally supported by coppers from poor people who pester us for a "little drop of horse oils for rheumatism." I recently opened it, and found 15/-, a useful help for us.

I am giving the question of supplying collecting boxes further consideration, and making enquiries as to cost of same, and shall be pleased, on receipt of request, to send one on.

The wives and sisters of veterinary surgeons might also be asked to help in forwarding the objects of the Fund by arranging afternoon concerts, whist drives, etc., amongst their friends.

It is of the utmost importance that these ladies should be informed of the existence of the Fund, as I am certain many in very poor circumstances could be helped if we could only get at them. Genteel poverty is harder on those who bear it than any other form.—Faithfully yours,

WM. SHIPLEY, Hon. Sec. & Treas.

OCTOBER 18, 1913

VOL. XXVI.

THE KINNARD APPEAL CASE.

The balance has once more turned against the Royal College. The decision, as usual in such cases, is given on the letter of the law and not on the broader issue of the protection of the public. This duty of protection is in large measure delegated to the Royal College, and in the preamble to the Act of 1881 the words used are "to distinguish between qualified and unqualified persons," while Clauses 16 and 17 define the lines which the unqualified man may not transgress without liability to a penalty.

Obviously this leaves the old principle of *caveat emptor* untouched, and leaves us facing our old troubles of the unregistered man and the medicine vendor. One outcome of this position is that it becomes essential to educate not only our own men, but the public who employ us. If all men were of equal capacity, this would be a simpler question, since our qualification would be much nearer to a fixed quantity than it is. But educational tests do not gauge a man's capacity nor his character, either in our profession or any other; and it is for us, individually and collectively, to help to maintain a standard of knowledge and of conduct which may strengthen the feeble protection afforded us by the law.

THE COUNCIL MEETING.

The work of our Council at the quarterly meeting contains several items of interest, besides the essential routine, which constantly varies in detail, if not in character. Under "Parliamentary Committee" comes a draft Supplemental Charter, which contains provisions for a shorter qualification period for the Fellowship Degree, and for a diploma in Veterinary State Medicine, both which proposals have been before the profession for months past. Three other clauses concern internal management, and are not considered controversial in character.

The remarks on the report of the Library and Museum Committee are corollary to the financial statements of the past three years—not that of the past quarter, which naturally shows a temporary amelioration. The most important question was the proposed revision of the preliminary examination schedule. The recommendation to adopt the revision was deleted from the report of the Committee, and the motion was withdrawn at the Special Meeting.

Many of us will agree with the opinion of Maj.-Gen. F. Smith—at the Manchester meeting N.V.A.—that the time has passed when we should follow closely the educational lines of the Medical Council.

ANTHRAX IN THE HORSE.

Subject.—A grey mare, half-bred, five years old. This mare was bought by me personally on April 20th in the plains of Aconcagua River.

History.—This mare worked in a mowing machine when I first saw her, then in general work on a *hacienda*. On the morning of May 3rd a messenger came to tell me the mare was very ill with pains similar to colic. I couldn't attend myself at once so sent my assistant, qualified in the Argentine. He reported the mare was dead. I told him to wait for me, and went at once. To all outward appearances nothing was strange in the aspect of the cadaver, and nothing to lead to any suspicion.

I opened the cadaver and found a great amount of fluid in the abdominal and pleural cavities. This was quite clear, but with a specific gravity of 1024. More especially was this fluid encountered in the pericardial sac, and here it had a slightly yellowish tinge. The intestines were in an infiltrated condition like one finds in the muscles of *charbon symptomatique*. I at once suspected anthrax, and under microscopic examination my diagnosis was confirmed by a French colleague practising here.

Please note. There are no Sanitary Laws, or Board of Agriculture, or County Councils in Chile.

The sequel was, the man who took off the skin was attacked with malignant pustule, and although treated under the best medical advice, to save his life it was necessary to sacrifice his arm.

Further proof was demonstrated in my own person, for nine days after in my right wrist I noticed, late in the evening, a part very red in colour *but no pain*. In the small hours of the morning I noticed that the parts surrounding were very œdematous. As soon as daylight came I consulted Dr. J. D. Eastman, M.R.C.S., M.R.C.P., who is the only medical man here with a British degree and he at once applied iodine. By this time the characteristic pustules had appeared in this form

Afterwards the whole part was burnt out with the thermo-cautery, and injections of tr. iodine were made at the rate of 40 a day. I made a good recovery in about three weeks, but the effects of the iodine or the cautery—I don't know which—have left me with no sensation in my right thumb and first finger.

P.S.—As I write this, two years after, the sensation has returned; but in a change of weather I still feel a contraction of the original wound.

WM. J. MOODY, F.R.C.V.S.

Santiago, Chile.

ABSTRACTS FROM FOREIGN JOURNALS.

GENERALISED MYCOSIS IN THE OX.

P. Langrand, a sanitary veterinary officer of Paris, records the following case in a cow. In life, the animal showed numerous subcutaneous nodules disseminated over the whole surface of the body, and involving the limbs. These nodules were not adherent to the skin, were very resistant, were round or oblong in shape, and ranged from the size of a pea to that of a walnut. An indurated lymphatic cord was found in the carpal region, uniting three of the nodules. The skin in the region of the lesions was intact, and there could be no suspicion of the presence of larval *ostridae*. The subcutaneous lymphatic glands were normal. The nodules were perfectly distinct from one another, and were particularly abundant upon the neck and shoulders. In the regions of the submaxillary space, the abdomen, and the perineum, they were somewhat separated.

The cow was emaciated and coughing. Palpation of the retropharyngeal, subglossal, and parotid glands did not reveal any adenitis.

Some nodules appeared to be more deeply situated in the tissues than others. Post-mortem, some were found in the thickness of the superficial muscles of the brisket, abdomen, and thigh.

Post-mortem Examination.—The lungs contained purulent centres, isolated or grouped, varying from the size of a nut to that of the fist. At first sight they resembled tuberculous lesions, with the exception that calcification was absent. Some of these centres opened into bronchi, which then contained yellowish and very thick pus. The young lesions were the most interesting, as close examination showed them to be composed of several concentric layers of concreted pus, alternately brown and yellow, gradually becoming more resistant as they approached the periphery. Five or six successive layers could be counted, surrounding a softened centre. The most external layer was fibrous, and sent out prolongations into the surrounding pulmonary tissue, which was generally healthy.

The small centres were all of the same type, and the subcutaneous and muscular nodules showed a structure in all points similar to them. The large centres were caseo-fibrous and grouped, and formed lumps which attained the size of the fist, and in general were badly defined. Upon section, they still showed stratification.

The subcutaneous and superficial muscular nodules, if large, did not contain pus. They gave the impression of an elastic tissue of a grey colour. Upon section, concentric zones appeared, five to ten in number, alternately clear and dark, surrounding a central island almost as resistant as the remainder of the nodule. There was no trace of calcification, and the nodules were of the caseo-fibrous type.

The lymphatic cord of the carpal region was ochre-coloured and clearly caseous.

The lymphatic glands of the system were healthy, except the left bronchial and one mediastinal gland. The mediastinal gland was the size of the fist, and was transformed into a vast nodule of concreted pus in concentric layers. The left bronchial gland showed, at its centre, a pea-sized purulent nodule. Neither of these glands showed any trace of calcification.

All the viscera were normal.

Microscopical Examination.—Numerous microscopical examinations were made, but in no case could acid-fast organisms be demonstrated in either the pulmonary tissue, the subdermal nodules, or the mediastinal gland. The left bronchial gland alone, in the course of ten preparations which were made from it, yielded two acid-fast forms which resembled tubercle bacilli. Eight inoculations—subcutaneous and intra-peritoneal—were made upon guinea-pigs, and the results, though various lesions were produced, were negative as regards tuberculosis.

Langrand minutely describes the histology of the subcutaneous and muscular lesions, which proved to be inflammatory nodules comprising four perfectly distinct zones. The central zone was degenerated, and was composed of necrosed lymphoid cells and fairly numerous giant cells. Circumscribing this zone were several concentric layers of lymphoid and epithelioid cells undergoing chromatolysis and protoplasmic fusion. These layers were separated from one another by a clear tissue which had formerly been fibrous, and which was stained a very faint pink by hæmatoxylin-eosin. The appearances suggested that the process of necrosis had been effected in successive periods, with intervals of arrest of necrosis between each. This theory explains, to the author's mind, the alternation of clear and dark layers which was observed. The third zone was composed of intact lymphoid and giant cells, with a fourth fibrous zone circumscribing the nodule.

Each subcutaneous and muscular nodule had only one centre, and the degenerated centre generally contained one or more blood-vessels.

The young pulmonary lesions contained the same elements and structure as those just described, with central blood-vessels. In most of them, staining by hæmatoxylin revealed the existence, at the centre of the nodule, of a vegetable parasite characterised by filaments and spores. The filaments were either separate or tangled together, varied in dimensions, were often undulating, and terminated by conical enlargements.

This champignon-like parasite was found in all the pulmonary lesions. In the subcutaneous and muscular lesions it was not so abundant, but was nevertheless found. Its appearance in the latter situation differed with the age of the lesions. In old lesions the mycelial fragments were modified into involution forms; in young lesions, on the contrary, the parasites were very little deformed, and were similar to those found in the lungs.

While not being able exactly to identify this parasite, Langrand records its discovery as proving the existence of a champignon, other than the blasto-

myces and the sporothrix, which is capable of invading the different tissues of the bovine organism. Despite the negative results of the examination for tuberculosis, he is not certain, in the first case, whether or not the invasion of the organism by the mycelium had been dependent upon a primary infection by the tubercle bacillus. If, however, the tubercle bacillus had previously been present in the tissues, it had certainly left hardly any trace behind.

Langrand records the case as indicating a complication in the practical diagnosis of subdermal lesions, which may be thought to be tuberculous when they are really due to a generalised mycosis. In this connection he draws special attention to the peculiar concentric striation which was visible in the nodules, and which first led him to suspect that the lesions were other than tuberculous.—(*L'Hygiène de la Viande et du Lait*).

W. R. C.

Royal College of Veterinary Surgeons.

QUARTERLY MEETING OF COUNCIL.

A Quarterly meeting of Council was held at the College, 10 Red Lion Square, London, W.C., on Friday afternoon, 10th Oct., 1913. Mr. J. H. Carter, President, occupied the chair, and the following members were present: Major-General Thompson, C.B.; Profs. Bradley and McCall, Sir John M'Fadyean, Mettam, and Shave; Messrs. Banham, Clarkson, Dunstan, Garnett, Lawson, McI. McCall, Mulvey, Packman, Price, Share-Jones, Shipley, Slocock, Sir Stewart Stockman, Sumner, Trigger, and Wharam; Mr. George Thatcher, Solicitor; and Mr. Fred Bullock, Secretary.

MINUTES.

The minutes of the last quarterly meeting of Council, which had been printed and circulated, were taken as read and confirmed.

APOLOGIES FOR ABSENCE.

The SECRETARY announced that apologies had been received from the following gentlemen regretting their inability to attend the meeting: Messrs. Walter Burt, J. S. Lloyd, Freeman Barrett, Joseph Abson, Frederick Hobday, McKinna, and A. W. Mason.

OBITUARY.

The SECRETARY read the Obituary List.

ADMISSIONS TO MEMBERSHIP.

The SECRETARY read the following list of members admitted to the College since the previous quarterly meeting of Council:—

London College. Messrs. W. A. Austin, C. E. W. Bryan, J. Blackburn, R. Daubney, R. T. Davis, C. Davenport, G. van de W. DeKock, G. O. R. Grey, D. C. Greene, A. Hoskin, V. J. Hare, H. Hicks, W. Kendrick, A. V. Nicholas, A. A. Pryer, J. M. L. Penhale, J. Southall, W. L. Sheffield, A. R. Smythe, G. M. Vincent, and J. A. Ward.

Edinburgh College. Messrs. J. Conner and R. S. Little.

Glasgow College. Messrs. J. S. Moncrieff, R. McK. Lawson, and T. T. Taylor.

Liverpool College. Mr. C. W. Elam.

Dublin College. Messrs. J. J. O'Neill, T. G. Browne, M. P. Hatch, J. J. Hegarty, J. P. McNally, J. J. Mills, J. J. Pomeroy, T. K. Reddin, C. M. Stewart, and M. Twomey.

CORRESPONDENCE.

The SECRETARY read a letter dated August 12th from Mr. Charles Roberts expressing to the Council on behalf of his family and himself, their sincere appreciation of the kind resolution of sympathy passed at the last meeting of Council.

The Secretary announced that a circular had been received in reference to the Sixth International Dairy Congress to be held at Bern, in June, 1914, asking for the appointment of a delegate, the fee being 20 marks. Section 1 of the Congress, Hygiene, dealt with (1) Conditions for the sanitary inspection of milk by Veterinary doctors; and (2) Is the systematic breeding of cows with a view to the largest production of milk detrimental to their health and vitality.

Mr. TRIGGER: I move that that letter referring to the Congress at Bern be brought forward at the next meeting of the Council. In the meantime we may be able to find out whether any member of Council will be attending that meeting and thus be able to represent us. There is plenty of time before next June.

Mr. LAWSON: I second that.

The resolution was agreed to.

The SECRETARY read the following letter:—

“86, Grange Lodge, Edinburgh,
10th July, 1913.

To the Secretary, Royal Coll. of Veterinary Surgeons.

Dear Sir,—I thank you very much for your kind letter of the 5th inst. informing me that the Council has no power to admit ladies to the examination for the diploma. I will be much obliged now by your being good enough to let me know to whom I shall apply in order to get ladies legally admitted to a course of study and to examinations necessary to secure a diploma which will enable them to practise the profession of veterinary physicians and surgeons with similar and equally valuable privileges to those granted to successful male students of those subjects. I am not particular at present whether this course and the examinations can be taken in any of the existing Colleges, or whether a separate College must be provided for them. That can be arranged afterwards, though I should prefer the use of the existing Colleges for the ladies' classes.—Believe me, yours faithfully,

(Signed) THOMAS H. GREIG.”

The PRESIDENT: Has any gentleman any remarks to make on that letter?

Sir STEWART STOCKMAN: I propose that it be referred to the Parliamentary Committee for report. I understand there is a desire amongst some of the members to have a discussion on it, but, as I pointed out in committee, it is a sleeping dog which was put to rest some years ago by a decision of the Scottish Courts, and when it was put to rest, it was done with the acclamation of the members of the profession. I think it would be a pity to raise a public discussion at present in this Council, seeing we already have the knowledge that when it was put to rest the profession were exceedingly pleased with the decision of the Court against women being admitted. I have no objection to the thing being discussed, but I think in the first place, so that we may know where it is leading us, we should refer it to a Committee before it is discussed in public. I do not much care which Committee it is.

Mr. SHIPLEY: I second that. I think it is a matter that ought to be decided once and for all amongst ourselves, and I should be glad if before that Committee meets the Secretary will inform us what legal decisions were arrived at in the previous case.

The resolution that the letter be referred to the Parliamentary and General Purposes Committee for report, was put and carried unanimously.

FINANCE COMMITTEE.

Mr. LAWSON read the following report of a meeting of the Finance Committee held on October 10th, 1913, and moved its adoption.

Chairman. It was resolved that Mr. Lawson be appointed Chairman of this Committee during the ensuing year.

Minutes. The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Financial Statement.—The Treasurer submitted his financial statement for the quarter, showing a balance in hand of £401 11s. 4d., and liabilities amounting to £132 6s. 2d.

It was resolved, that the financial statement be approved, and that the Treasurer be ordered to pay the liabilities shown, together with cheques for monthly salaries, petty cash, fidelity insurance, Fellowship examination expenses, gas, electric light.

Mr. TRIGGER seconded the motion for the adoption of the report, which was carried unanimously.

REGISTRATION COMMITTEE.

The SECRETARY read the report of a meeting of the Registration Committee, held on Thursday, October 9th, 1913, which stated that it was resolved that the President be appointed Chairman of the Committee during the ensuing year. Twenty cases were considered by the Committee, some of which were ordered to stand over for further evidence, and in others it was resolved that no action be taken. In the case of Glover, a non-member using the title M.R.C.V.S., the Solicitor reported that a prosecution had been instituted and a conviction obtained, the defendant being fined £10 and three guineas costs. The Solicitor reported that an appeal in the case of Kennard, canine surgery, was pending. In the case of Leighton, the Solicitor submitted correspondence he had had with the Local Government Board for Scotland, and it was resolved:

(a) That the Local Government Board for Scotland be asked to withdraw the use of the title "Veterinary" so far as relates to the appointment of Dr. Leighton.

(b) That the letter conveying the above request be first submitted for approval to a Sub-Committee consisting of the President, Sir John M'Fadyean, and Mr. Mulvey.

In another case it was resolved that the matter be referred to the Solicitor for investigation, with power to prosecute if practicable. In a case of advertising, it was reported that a disclaimer had been received, but it was resolved that the Secretary be instructed to obtain an undertaking.

Correspondence. (a) A letter was received from Mr. W. H. Edwards, submitting an explanation with regard to the issue of a circular, and undertaking that the offence should not be repeated.

(b) Other letters were submitted, and the Secretary was instructed as to the replies to be sent.

Restorations. Applications for restorations were received from Mr. Robert Bell and Mr. John Frederick Badger Moody, whose names had been removed from the Register of Veterinary Surgeons under Section 5, Sub-section (4) of the Act.

The applications were found to be in order, and it was resolved that the names of Robert Bell and John Frederick Badger Moody be restored to the Register of Veterinary Surgeons.

On the motion of the President, seconded by Major-General Thomson, the report was adopted; and on the motion of Mr. Mulvey, seconded by Major-General

Thomson, authority was given for the seal of the College to be affixed to the order for prosecution mentioned in the report.

EXAMINATION COMMITTEE.

Mr. MULVEY read the following report of a meeting of the Examination Committee, held on October 9th, 1913:—

Chairman. It was resolved that Mr. W. J. Mulvey be appointed Chairman of this Committee during the ensuing year.

Minutes. The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Reports on July Examinations. The reports by the Delegates, the Chairmen of the Boards of Examiners, and Local Secretaries were read and considered.

It was reported that candidate No. 1 in Class C at Liverpool had been dismissed from the written examination for copying.

It was resolved:

(a) That the reports on the July examinations be approved.

(b) That the dismissed candidate be permitted to attend the next examination on the same conditions as a rejected student.

Educational Certificates. Educational certificates numbered 1354 to 1371 were submitted and approved.

Jubilee Memorial and Bursary Prize. The following report by Mr. J. T. Edwards, the holder of the Jubilee Memorial and Bursary Prize, was received and ordered to be entered on the minutes:

"To the President and Council of the Royal College of Veterinary Surgeons.

Gentlemen,—As requested in the conditions of holding the Jubilee Memorial Prize I have the honour of presenting herewith a report as to work done during the past year.

I commenced attendance at the Ecole Vétérinaire, Alfort, on the 15th November, 1912, and with the exception of about a fortnight's vacation at Easter-time, I have been in continuous daily attendance up to this date.

During this period my aim has been to embrace as far as possible the general work of the School—lectures and practical work. I have thus put in an appearance at the lectures of the final year for the most part, and also visited the clinique and post-mortem room of the School.

In the case of the clinique more especially, however, I found after some weeks' attendance that the system employed, though it may be very excellent from the point of view of the student, was not carried out in such a way as to be beneficial to the spectator. This is indeed as it is intended to be. I was thus led to believe that I could more profitably spend a large part of my time by doing some special work at the school, and with this end in view I asked for permission from the Director, Prof. Vallée, to work in the laboratory for infectious diseases, and was readily allowed to do so.

During the greater part of each day I have thus worked in this laboratory, and have undertaken research work under the supervision of Prof. Vallée. This work has borne out chiefly on some anaerobic bacteria, the acid-fast bacilli, and streptococci. During the whole of my stay I have been granted a gratuitous and unlimited supply of laboratory material and experimental animals. I have therefore been afforded excellent opportunities of accustoming myself in French bacteriological methods. As far as this subject is concerned the French are artistic and untiring workers.

In conclusion, I beg to be allowed to record my appreciation of the way in which I have been treated by members of the staff and by students alike. My sincerest thanks are due to Prof. Vallée, who has ungrudgingly

given me advice, in a subject in which he is so highly distinguished, at all times when he has been able to relinquish the duties of a busy directorship.—I am, gentlemen, your obedient servant,

J. T. EDWARDS."

On the motion of Mr. Mulvey, seconded by Mr. Packman the report was adopted.

Prof. METTAM: I think there is one thing that should go forth from this Council in connection with the passing of that report, and that is that we should express our great appreciation of the facilities which have been offered by the Ecole Vétérinaire to this Bursar of ours. I think it is only due to the various authorities on the Continent who permit our scholars to go to their schools that we should show our appreciation of their kindness to us, and I move accordingly that a letter be sent to Prof. Vallée, signed by the President, conveying our appreciation of his services.

Sir JOHN M'FADYEAN: I second that.

The PRESIDENT: I think that will be endorsed by every member of this Council.

The resolution was carried by acclamation.

PARLIAMENTARY COMMITTEE.

Mr. GARNETT read the following report of a meeting of the Parliamentary Committee, held on October 9th, 1913:—

Chairman.—It was resolved that Mr. F. W. Garnett be appointed Chairman of this Committee during the ensuing year.

Minutes.—The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Correspondence.—(a) A letter was received from the Secretary of the Central Veterinary Society conveying a resolution with regard to the Veterinary Operations (Anæsthetics) Bill. In view of the fact that the Bill is no longer before Parliament, it was resolved that the letter be allowed to lie on the table.

(b) A letter with regard to the standardisation of tuberculin and mallein was received from the Board of Agriculture, and ordered to lie on the table.

New Supplemental Charter.—A draft Supplemental Charter containing the four following articles was submitted and considered:—

1. That in future the Annual General Meetings of the Members of the said College shall take place on any of the first seven days in the month of June in every year as may be fixed by the Council of the said College, provided that the date of such meeting shall be duly advertised as directed in the Charter of One thousand eight hundred and forty-four.

2. That notwithstanding anything in the Charter of one thousand eight hundred and forty-four, the number of Vice-presidents to be elected by the members of Council from their own number at the first meeting of Council after the annual general meeting of members, shall, at and after the meeting to be held in July, 19 , be restricted to two.

3. That the members of the said College shall be eligible to sit for the special examination or examinations instituted for the Diploma of the Fellowship Degree at the age of twenty-three years, instead of twenty-five years, provided that they shall have *bona-fide* practised their profession of veterinary surgeon for not less than two years, and shall also have complied with such rules and regulations as the Council of the said College shall from time to time consider expedient.

4. That the Council of the said College shall have power to institute a Diploma in Veterinary State Medicine, and to approve teachers, appoint examiners, and make bye-laws governing the award of the same.

It was also resolved (a) that the following clause be added:—

That in future when a vacancy or vacancies shall occur in the number of members of Council from any cause except that of going out of office by rotation, there shall be elected at the next annual general meeting a sufficient number of persons to supply the places of the members retiring by rotation and such vacancy or vacancies, and the eight persons who shall receive the highest number of votes shall take the places of the members retiring by rotation, and the occasional vacancy or vacancies shall be filled by the person or persons receiving the next highest number or numbers, and every person who in consequence of an occasional vacancy shall be elected a member of the Council shall be only a substitute for the person whose place he may supply, and shall continue in office only for the same period as the person whose place he may supply would have continued if he had not vacated the office before the time at which he must have necessarily gone out of office. In case of more than one occasional vacancy at any one election the vacancies shall be filled according to the number of votes obtained, the highest number entitling the owner to the vacancy having the longest term to run. In cases of two or more persons obtaining an equal number of votes for a vacant position, the person whose name shall have been longest on the Register of Veterinary Surgeons shall be considered to have obtained the highest number of votes.

(b) That the Solicitor be instructed to revise the draft, where necessary, for submission to the Privy Council, and that the Seal of the College be affixed to the petition.

Mr. GARNETT: I now move the adoption of the report of the Parliamentary Committee, the principal matter referred to in it being the new Supplemental Charter. In accordance with a resolution of the Council, authority was given to the Committee to deal with points in this Supplemental Charter which were not of a controversial nature, and all of which had been before the Council. That has been done, and subject to your approval and to a revision of the draft by the Solicitor, we ask you to pass it to-day; and then we will have to pass a special resolution that the Seal of the College be attached to it, and it will be presented to the Privy Council in the ordinary course. I do not think there is any matter of what can be considered a controversial nature in any way dealt with in the new Supplemental Charter.

Mr. LAWSON: I second the motion.

Mr. TRIGGER: There is nothing of a controversial nature so far as I know in the report, and I am not going to raise any point of a controversial nature. But there are just one or two little matters that I want to deal with. The Solicitor will remember that in connection with our last Charter we had to depend upon the preamble for certain powers. I venture to hope that that has been remedied in the present Charter, and that any points which it is necessary to bring into the body of the Charter are sufficiently emphasised there. I have always looked upon that as being more or less of a blot on our last Charter in that respect. I do not know whether that has been considered by the Committee, and in case it has not I draw attention to the point. Then I very cordially approve of the alteration with regard to the appointment of two Vice-presidents only, but I think it is an omission not to say "of whom the retiring President shall be one," because I think the first man who should occupy the Chair in the absence of the President should be the retiring President. I think the retiring President should be one of the Vice-presidents for the ensuing year. I do not care whether you make it two, of whom the past President shall be one, or whether you make it three, of whom the retiring President shall be one. I think if you make it "two, of whom the retiring President shall be one," it

would practically bind the Council to the President for the next year instead of having two to choose from. Anyway, I think we should have the retiring President as the senior Vice-president, because I think he is the proper man to occupy the Chair during the ensuing year as the ex-President in the absence of the President. Then there is one other point that I should like to refer to, namely, that the age for the Fellowship examination should be 23, and that the member should have been two years in practice. Some of us think that is very short, but I suppose the Committee have thoroughly considered it. That is very short unless they have been Professors at the College, and then they need not have been in practice. Professors become rather cheap if you take a young man of 21 and call him a Professor. I do not know what the members think of it, but it seems to me rather young.

Dr. BRADLEY: That is taken out.

Mr. TRIGGER: Not in the draft read to-day.

Mr. GARNETT: Yes, it is taken out.

Mr. TRIGGER: I can only say that in the draft I read to-day, which the Chairman kindly lent me to read through, it was there. The only question I think that should be considered is, whether it should be three years instead of two before you allow them to go in. I do not think 24 years instead of 23 is keeping the people any too long. Anyhow, I make the suggestion for what it is worth. I think the suggestion about the Vice-presidents should be considered. I think those are all the points I want to raise; I do not want to raise any controversial points, or press anything I have said. I have simply thrown them out for the consideration of the Council. I think two years is a very short time, and I suggest that should be altered to three. Perhaps you will allow me to move a resolution afterwards if I desire to do so.

Mr. SUMNER: I should like to appeal to the Solicitor with a view to condensing the fifth, the terminal, Clause. Could not a form of words be devised that would give power to this Council to allocate the results of the voting as they may seem fit, without that long recital of the various points?

Mr. THATCHER (Solicitor): I am afraid not. I tried to make it as short as I could to sufficiently express the intention.

Mr. SUMNER: My point is that the Council may have power to allocate the seats on the voting as it saw fit from time to time. We are asking for new powers under the new Diploma without giving all the regulations appertaining to the Diploma.

Mr. THATCHER: Without going into the question of merits, the danger of that would be this, that it would enable the Council to say which members should come on to their body and which should not. The election of members of Council is one which, in my opinion, should be left absolutely to the members of the profession. (Hear, hear.)

Mr. GARNETT: In reply to Mr. Trigger's two points, first that the number of Vice-presidents might be increased to three from two, it was a special resolution of this Council, that the Vice-presidents be two in number. I am quite prepared to accept an amendment, and to provide in the Clause that one of such Vice-presidents shall be the retiring President. I do not see any harm in that, in fact I think it would work very well.

The PRESIDENT: Supposing the President were to die during the year?

Mr. GARNETT: Then the previous President in the year before would automatically become one of the Vice-presidents. I think as it stands now it will work out very well in practice.

Mr. PRICE: What would be the objection to having three Vice-presidents?

Mr. GARNETT: Because we have already passed a resolution at this Council that the number of Vice-Presidents should be reduced to two, and according to our bye-laws we cannot rescind that motion within twelve months.

Mr. TRIGGER: Then I shall have to move that it read:—"Two, of whom the retiring President shall be one."

Mr. GARNETT: The other point raised was with regard to the number of years that should elapse after a man is qualified before he takes his Fellowship. That also was a resolution that was passed by this Council, and we had to carry out the directions of the Council, and we cannot rescind that again for twelve months. With regard to the point raised by Mr. Sumner, it was felt by the Committee, in fact it was a unanimous vote I think in the end, that when there were a larger number than the ordinary eight vacancies, owing to death vacancies or retirements of other people, the lowest number of the successful candidates should succeed to the vacancies caused not in the ordinary nature of events, that is, to the exceptional vacancies. An illustration of that was very forcibly brought before us this year, when there were nine vacancies, eight retiring by rotation, and one death vacancy. Mr. Shipley, who had obtained the largest number of votes, was by ballot selected to fill the death vacancy, so that he has to submit himself again for election next year, although he obtained the largest number of votes. Perhaps the man at the bottom may have got in only by an odd vote or two, and the Committee felt it was very desirable that provision should be made in that respect, and it was left to the Solicitor to draw up the Clause that I have read to you to provide for it.

Mr. TRIGGER: I understand we cannot alter the age without altering the bye-law?

Mr. MULVEY: I do not quite agree with what has been said with regard to the resolution of the Council at its last meeting taking the form of a bye-law. In my opinion it is not a bye-law. It was simply an instruction to the Committee on what lines they were to draw up this proposed Charter in order to submit it to this Council. I say in my opinion it does not take the form of a bye-law. That is to say, there is no reason at all why an alteration should not be made.

Sir JOHN McFADYEAN: Now?

Mr. MULVEY: Yes, that is my view.

The PRESIDENT: You mean instead of delaying it for twelve months?

Mr. MULVEY: Yes.

Mr. SHIPLEY: Do I understand that by passing this report we authorise the Seal of the College to be affixed to this new Charter before we see it? because I am not satisfied about it. As far as I am concerned I am satisfied that the Committee have done the best they can, and I quite appreciate the work the Chairman has done in connection with it, but I certainly should not be prepared to vote for a supplementary charter to be sent to anybody until I have seen and read what the contents are. I should therefore like to propose that a draft of the new Charter be printed and circulated among the whole of the members of the Council for their consideration.

Mr. GARNETT: In reply to Mr. Shipley, I might say that the whole of the resolutions embodied in the draft Charter that is now submitted to you have been discussed by the Council. They were direct instructions that were passed by this Council after full discussion, and simply sent on to the Committee to formulate into legal phraseology, with the single exception of the one which Mr. Thatcher has drafted making provision for the retiring members of the Council. That is the only one that has not been fully discussed and passed by the Council. It was an instruction to the Committee to

draft this Charter on certain definite lines, and passed by the Council with that exception.

Mr. SHIPLEY: If I may say so, in reply, I really think the members of Council should be put in possession of a printed copy of this Charter before we let it go. Mr. Garnett knows exactly what goes on at the Parliamentary Committee, but I am not a member of the Parliamentary Committee. I have seen a certain amount of bungle made in the Bills before, and I think we ought to have it before us before we let it go.

Mr. MULVEY: I should like to appeal to Mr. Thatcher to explain to us the exact position.

Mr. THATCHER: The exact procedure is this. A petition has to be prepared setting out what is required, and setting out the reasons why such things are required. That is presented to the Privy Council. Accompanying that is a draft of the Charter that it is proposed the Privy Council should grant. The Privy Council then enquire if there is any opposition on the part of any person to the Charter being granted in those terms, or at all. Everybody has the opportunity then of going before the Privy Council and stating their reasons generally in writing against the Charter, or against certain points in the Charter. That is considered by the Committee of the Privy Council to whom such things are specially remitted. If they consider necessary they can call evidence, and hear counsel, and so on before coming to a decision. When they come to their decision, the draft Charter itself is then for the first time considered, because up to this period all that has been considered is the petition. The Charter is then sent to the draughtsman particularly appointed for the purpose, and if he sees anything in the draft that he objects to he says so, and then the legal representatives of the petitioners have to appear either to justify or to accept what he says. So that you see, Mr. Shipley, it is quite open to anybody to object to this Charter until the actual moment His Majesty's Seal is affixed to it.

Mr. SHIPLEY: If I may be allowed to say one thing more, my object in raising the point is that there should be no objection offered to the new Charter, and that we should not have to go to oppose the Charter, or that anyone should have an opportunity of opposing it. Let us consider it ourselves and know what we are petitioning for before we let it go. (Hear, hear). That is the only thing I ask for.

Mr. MULVEY: The question I asked was this: Has this Council power at this meeting to alter any clause or interpolate a fresh clause before this is sent forward?

Mr. THATCHER: Certainly.

Mr. MULVEY: That is all I wanted to know.

Mr. GARNETT: Most certainly, so long as they are not directly opposed to resolutions which have already been passed by this Council. There are certain principles embodied in this Charter which the Council has already approved of by resolution, and they cannot be rescinded within twelve months. But I have no objection whatever to this being postponed, although there are very strong reasons of urgency. Each clause, with one exception, has been fully discussed by the Council.

Mr. SUMNER: I think no harm could be done by giving every member of the Council a copy of it, and deferring our consideration of this supplemental Charter until the next meeting.

The PRESIDENT: Do you mean to postpone the whole thing until the next meeting?

Mr. SUMNER: Yes, to postpone sending the petition until every member of Council has had time to digest the new clauses in it. Practically I second what Mr. Shipley has moved.

Sir JOHN M'FADYEAN: Might we ask the Secretary or the Solicitor to read out the resolutions?

The PRESIDENT: Which one is it you refer to?

Sir JOHN M'FADYEAN: The Bye-law which says that any motion which has been before the Council and has been voted upon shall not be brought up again in less than twelve months.

The SECRETARY: It is No. 11a. "No motion which has been rejected by the Council shall be again moved at a subsequent meeting held within a shorter period than twelve months except with the consent of the majority of the members present."

Sir JOHN M'FADYEAN: I am sorry I could not agree with what Mr. Garnett said about that, because there has been no formal motion about this, and there has been nothing rejected. I take it that the Council can do just as it pleases about the draft Charter. (Hear, hear). They can pass it as it stands, or amend it now, or refer it back, or postpone it for the consideration of the next meeting.

Mr. TRIGGER: You gave me permission, sir, to move a resolution later on about the Vice-presidents, but in view of what has taken place I confess I should like to have a copy of the Charter, and read it through carefully at home, and read the supplemental Charter with it. I should like to see them side by side, and think over whether other important matters may not be brought in. The last Charter was hurried through for two purposes, and we got something that we did not want, and we left out other things that we did want. I therefore move that the matter be adjourned to the January meeting, and that each member of the Council who has not already had a copy of the supplemental Charter be furnished with one. I suppose the members of the Parliamentary Committee have had their copies.

The PRESIDENT: Could you put it in this form, that the report be adopted, with the exception that this matter be postponed till the next quarterly meeting?

Mr. GARNETT: That the discussion on the Charter be deferred for three months.

Mr. TRIGGER: Instead of adopting the report, I move that the decision be deferred for three months until the January meeting.

Mr. SHIPLEY: I made a proposition, which has been seconded by Mr. Sumner, that the question of this Charter be referred to a Committee of the whole Council.

Sir JOHN M'FADYEAN: No, no.

Mr. SUMNER: That every member of the Council should have a copy of it.

Mr. SHIPLEY: Yes, that is what I mean. There is no reason why we should not have an early meeting to consider it. I do not wish to hinder it in any way whatever.

Mr. GARNETT: If we propose that the minutes of the Parliamentary and General Purposes Committee be adopted, with the exception of that portion referring to the supplemental Charter, which shall be referred back to the next quarterly meeting, with instructions that copies of the supplemental Charter be circulated among the members of Council, that will carry out the wishes of the members.

Mr. SUMNER: Yes, that is it.

The PRESIDENT: That is the omission of Clause IV. This resolution was then put and carried unanimously.

PUBLICATION COMMITTEE.

Mr. SHARE-JONES read the following report of a meeting of the Publication Committee held on October 10th, 1913:—

Chairman.—It was resolved that Mr. J. T. Share-Jones be appointed Chairman of this Committee during the ensuing year.

Minutes.—The minutes of the previous meeting having been read, printed, and circulated, were taken as read and confirmed.

Publication of Register.—It was resolved—(a) That, subject to the approval of the Council to the new regulations for the Fellowship Degree and for the Diploma in Veterinary State Medicine, proposed to come into operation on the date of the obtaining of the new Charter, these regulations be published in the Register for 1914.

(b) Appendix VII. Highland and Agricultural Society's Certificate holders. That the Registrar be instructed to communicate with Principal McCall to obtain his assistance in the revision of the list of holders of the Highland Society's Certificate.

(c) That the Registrar be ordered to arrange for the printing and publishing of 500 copies of the Register, 1914, after revision.

Prof. SHARE-JONES: I move the adoption of the report, and in doing so I should like to refer to a very interesting fact which came to light during our brief deliberations this morning, and that is, that Mr. Nettleship, who is a member of this College, has obtained the high honour of Fellowship of the Royal Society. I think since the fact came to light, it is my duty to mention it here, because honours of that kind have not been too common in our history. (Hear, hear).

Mr. PACKMAN seconded the motion, which was carried unanimously.

PRELIMINARY EXAMINATION COMMITTEE.

Mr. MULVEY read the following report of a meeting of the Preliminary Examination Committee, held on October 10th, 1913, and moved its adoption.

Preliminary Educational Examinations. (a) The Secretary reported that, as instructed at the previous meeting, he had communicated with the College of Preceptors, the Educational Institute of Scotland, and the Intermediate Education Board for Ireland, all of whom were prepared to examine veterinary candidates on the present standard until the end of the year 1914, it being understood that until that date candidates would have a choice of either the old or the new standard.

(b) The Secretary submitted a copy of Schedule I, revised in accordance with the recommendations adopted at the last meeting of Council, and which had been suspended for the required period of three months.

It was resolved to recommend, That the Schedule, as revised, be adopted, to come into force on January 1st, 1915.

Dr. BRADLEY: I second that.

Sir JOHN M'FADYEAN: This requires three months' suspension.

The SECRETARY: It has been suspended three months.

Sir JOHN M'FADYEAN: The decisions you came to at the meeting the other day cannot have been suspended yet.

The SECRETARY: No.

Sir JOHN M'FADYEAN: This is not the time to discuss it then, but at the next meeting. I want to make it clear that by adopting this report we do not dispense with the necessity of considering Mr. Mulvey's motion, which is down for the special meeting.

Mr. MULVEY: Oh no. It has nothing to do with it. That will come on at the special meeting presently.

Sir JOHN M'FADYEAN: But in the ordinary course of business, if we adopt this report then it becomes a bye-law.

Mr. MULVEY: Yes, but I am only now proposing that you should adopt this recommendation of the Committee, and that at the special meeting we will bring forward the Schedule.

Sir JOHN M'FADYEAN: Although possibly the proper place at which to raise the question of the advisability of raising the standard of the Preliminary Educational Examinations would be at the special meeting, I feel impelled to raise it now, and to point out to the Council that the raising of the standard of the preliminary

educational examinations is a step demanding the most serious consideration before it is undertaken. Nobody can be more desirous than I myself to see the general education of veterinary students improved, but I think our first duty is to see that we do not do anything that deprives the country of an adequate number of veterinary surgeons. Everybody must admit that it would be possible to raise the standard of the preliminary examination too high. I think everybody will admit that it would, for example, be too high if it cut down the number of those obtaining the diploma annually to ten. I suppose there will be no argument about that, because in the course of a few years it is quite obvious there would not be a sufficient number of veterinary surgeons in the country to meet the requirements of stock-owners and owners of animals. I suppose that those who are prepared to recommend that at the end of 1914 we raise the standard of the preliminary examination to a considerable extent have thought the matter out, and calculated that this will not lead to a very serious reduction in the number of veterinary students, and in the number of those entering the profession. I have thought a great deal about it myself, and I am not at all satisfied that any serious increase in the difficulty of passing the preliminary examination would not have a very important effect in still further reducing the number of those aspiring to enter the profession. It might even happen that we should, after the experience of a year or two, have to rescind this resolution and go back to the lower standard. Now that would be a most undesirable thing. It would be far better, I think, that we should proceed very cautiously. In urging caution I am not thinking about the interests of this profession, and I can honestly affirm I am not thinking about the interests of the schools, although I may point out that if there is any further great reduction in the number of students this body may be landed in bankruptcy, and the schools will certainly be very seriously handicapped further than they are at present, and proper veterinary education would thereby be interfered with. But the point I desire to press is that the Council should consider whether, if there is any likelihood of raising the standard of the preliminary examination two years hence, and that would still further reduce the number of those entering the profession, it is desirable to move in that direction.

The PRESIDENT: I will just ask Mr. Bullock to read the resolution which was adopted at the last meeting of Council.

The SECRETARY: At the last meeting of Council the report of the Preliminary Examination Committee was passed, in which the following two recommendations were included:—“(a) That candidates presenting themselves for the first professional examination in and after December, 1915, be required to produce a certificate of having passed one of the preliminary educational examinations in accordance with the revised regulations of the General Medical Council, provided that, in the case of candidates whose educational certificates are dated earlier than November, 1914, the present regulations shall apply. (b) That Schedule I. be revised in accordance with the above recommendation.”

Sir JOHN M'FADYEAN: Mr. Mulvey suggests that under the new regulations certain examinations in which at present all the subjects must be passed at once, may be passed at two or more times. But is that really a suggestion that we are not going to raise the standard of the preliminary examination? None of us can delude ourselves about that. Of course the effect of the proposal would be very materially to raise the standard of the examinations. During recent years we all know that at least 70 per cent. of the candidates have come in under the educational certificate of the Educational Institute of Scotland. I believe that body is not under any misapprehension as to the effect of the new regula-

tions of the General Medical Council. I venture to say that it will increase the rejections of candidates as compared with the last few years by 50 per cent. The Council may, in its wisdom, decide that the standard of the preliminary examination must be raised, but I beg of them not to come to that decision under the delusion—because I am sure it would be a delusion—that the number of candidates is not going to be reduced in the future by raising the standard.

Mr. MULVEY: I want to make one remark, sir. Sir John M'Fadyean was present at the last meeting of Council, at which this resolution was passed. Personally, I feel it is a great pity that he did not take exception to it, and state that if the examination was to be taken in two parts he was willing it should go on. I think it is a great pity that the time of the Committee should be spent in going through this, and then Sir John oppose it now.

Mr. SHARE-JONES: I should like to ask, before we enter into this debate, in which there are obviously two sides, whether it is in order that it should be brought up now?

Mr. THATCHER: The only point on which order could arise would be on the last paragraph of the report.

Sir JOHN M'FADYEAN: That is the point on which I supposed I was in order.

Mr. THATCHER: Without going into the question of order, would it not be more convenient to discuss it at the special meeting when the matter is directly in point?

Sir JOHN M'FADYEAN: That is the preliminary point I raised—whether if we adopted this report it would not still further commit the Council to this step.

Mr. THATCHER: I have no doubt the Chairman of the Committee would be quite willing to delete this for the present, and have the whole question discussed at the special meeting, which would be far more convenient.

Sir JOHN M'FADYEAN: That would meet my view.

Mr. MULVEY: I have not the slightest objection to that course being pursued, if it is considered desirable.

Mr. TRIGGER: I think that would be the best course to adopt, because there are many of us that are not members of the Examination Committee. I have never been a member of it. I should like to see it referred back to a Committee of the whole Council, where we could all take part in the discussion at the special meeting. I move that it be referred back to the special meeting of the whole Council, unless Mr. Mulvey delete that last paragraph.

Major-General THOMSON: I confess I do not understand what Mr. Trigger is driving at. He suggests that it should be referred back to a special meeting of the whole Council. I see no reason why it cannot be referred back to the special meeting of Council about to sit, in which case we shall deal with it there.

Mr. TRIGGER: That is what I mean.

Mr. MULVEY: To meet with the wishes of certain speakers, I move that permission be given to leave out the words following after "period of three months," namely, "It was resolved to recommend, that the Schedule, as revised, be adopted, to come into force on January 1st, 1915." I move to leave out those words.

Sir JOHN M'FADYEAN: That was the only paragraph in the report which appeared to me to justify me in raising the point at this stage.

Prof. SHARE-JONES: May I ask whether that was not passed at our last Council meeting?

Mr. MULVEY: Yes, it was.

Sir JOHN M'FADYEAN: May I be allowed to point out it was not. I have before me printed in the minutes what was resolved at the last meeting—"It was resolved to recommend (a) That candidates presenting themselves for the first professional examination in and after Dec., 1915."

Mr. MULVEY: That is right.

Sir JOHN M'FADYEAN: The revised bye-law as recommended by the Committee now is to come into force in January, 1915.

The SECRETARY: That is the same date really.

Mr. SUMNER: They would be eligible for the next examination in 1915.

It was resolved that the minutes should be adopted, subject to the deletion of the last paragraph, namely, "It was resolved to recommend that the schedule, as revised, be adopted, to come into force on January 1st, 1915."

LIBRARY AND MUSEUM COMMITTEE.

Dr. BRADLEY read the following report of a meeting of the Library and Museum Committee, held on Oct. 10th, 1913:

Chairman. It was resolved that Dr. O. C. Bradley be appointed Chairman of this Committee during the ensuing year.

Minutes. The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Presentations and Additions. The Secretary reported that since the date of the previous quarterly meeting of Council, the following presentations had been made to the Library:—

And it was resolved, that a vote of thanks be conveyed to the respective donors:—

How to Diagnose Smallpox, by W. McG. Wanklyn, B.A., M.R.C.S., L.R.C.P., D.P.H.; On a case of Blindness from Optic Neuritis without Intracranial Disease in a pedigree Bull, by E. Nettleship, F.R.S., M.R.C.V.S., and A. C. Hudson; Calendar of the Royal College of Surgeons of England, 1913; Calendar of the Edinburgh University, 1913-1914; Annual Report of Proceedings under the Diseases of Animals Acts, the Markets and Fairs (Weighing of Cattle) Acts, 1912; Annual Reports of the Department of Agriculture, Nyasaland Protectorate, for the years 1912 and 1913; Report on the working of the Veterinary Department of the Rangoon Municipality, 1912-13; Report on Higher Education in the State of New York for the school year ending July 31st, 1912.

U.S. Department of Agriculture: Twenty-Eighth Annual Report of the Bureau of Animal Industry, 1911; Important Poultry Diseases, by D. E. Salmon, D.V.M.; Regulations governing the preparation, sale, barter, exchange, shipment, and importation of Viruses, Serums, Toxins, and analogous products intended for use in the treatment of Domestic Animals.

New South Wales Department of Agriculture: Ten Years' Egg-Laying Tests at Hawesbury Agricultural College and Experiment Farm, Richmond, N.S.W. Results Analysed and Reviewed by A. A. Dunncliff, Junior.

Memoirs of the Department of Agriculture in India, Vol. II., No. 1.; *The Bloodstock Breeder's Review*, Oct., 1913; *The Rhodesian Agricultural Journal*, June and August, 1913; Bulletin of the Yellow Fever Bureau, April, 1913; *The Journal of the Board of Agriculture* (with supplements), July, August, and September, 1913; Catalogue of Periodical and Serial Publications filed in the Library of the Board of Agriculture; Leaflets of the Board of Agriculture and Fisheries; Orders of the Board of Agriculture and Fisheries; *Revue de Pathologie Comparée*, June and July, 1913; *The Journal of Comparative Pathology and Therapeutics*, June, 1913; *The Veterinary Journal*, *The Veterinary News*, and *The Veterinary Record* for the quarter.

Additions to the Library. Tropical Diseases Bulletin, July, August, and September, 1913; Tropical Veterinary Bulletin, August, 1913; Reports to the Local Government Board on Bacterial Food Poisoning and Food Infections, by Dr. W. G. Savage.

Purchases. The Secretary reported that the following books had been purchased for the Library:—Tropical Diseases Bulletin, July, August, and September, 1913; Tropical Veterinary Bulletin, August, 1913; Report to the Local Government Board on Bacterial Food Poisoning and Food Infections, by Dr. W. G. Savage.

On the motion of the Chairman, the Secretary was instructed to apply to the Carnegie Foundation for free copies of the following two volumes:—Medical Education in the United States; Medical Education in Europe.

The Secretary was also instructed to write to the Editors of the *British Medical Journal* and the *Lancet* to request that the Library of the Royal College of Veterinary Surgeons should be placed on the free list.

Museum. The question of cleaning and arranging of specimens in the Museum, in view of the approaching International Veterinary Congress, was considered.

And it was resolved to recommend that arrangements be made for the specimens in the Museum to be cleaned and put in order at a cost not to exceed twenty guineas.

Mr. BRADLEY: I move the adoption of the Report.

Mr. SLOCOCK: I second it.

Mr. MULVEY: Before you put that resolution, I would like to ask whether it is seriously contended that our collection in the Museum is worth the expenditure, and whether it would not be better, in view of the forthcoming Congress, that we lock the door and do not let anyone know we have a Museum. (Hear, hear).

Sir JOHN McFADYEAN: And lose the key! (Laughter and hear, hear).

Mr. SHARE-JONES: That is a very good suggestion.

Mr. LAWSON: I second that.

The CHAIRMAN: It is moved and seconded that the report of the Library and Museum Committee be adopted, with the exception that the door of the Museum be locked. (Laughter).

Mr. GARNETT: I propose as an amendment that the minutes be adopted, subject to that portion referring to the expenditure on the Museum being referred back to the committee for further consideration. (Hear, hear).

Mr. LAWSON: I second that.

The amendment was put, and carried unanimously.

HONORARY ASSOCIATES COMMITTEE.

Professor METTAM read the following report of a meeting of the Honorary Associates Committee, held on October 9th, 1913:—

Chairman. It was resolved that Prof. Mettam be appointed Chairman of this Committee during the ensuing year.

Minutes. The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Honorary Associates. Nominations were submitted and considered, and it was resolved, that the Secretary be instructed to circulate to the members of the Committee lists of the names suggested, in time for the next meeting in January.

On the motion of Prof. Mettam, seconded by Principal McCall, the report was adopted.

BYE-LAWS SPECIAL COMMITTEE.

Mr. GARNETT read the following report of a meeting of the Bye-laws Special Committee held on the 9th October, 1913:—

Bye-laws. The Committee reconsidered the bye-laws recommended at the previous meeting in accordance with the instructions of the Council.

And it was resolved to recommend, that the following revised bye-laws be adopted:—

53a *Exemption.* Students who have obtained a Degree in Arts, Science, or Medicine of any University in the United Kingdom, or the Diploma of Licentiate of the

Royal Colleges of Surgeons and of the Royal Colleges of Physicians, and who at the respective examinations for such Degree or Diploma, have passed in chemistry and physics, and also in biology (zoology and botany), are exempted from attendance at the first year's course of lectures and from the examination at the end of that year, provided that each student so exempted shall be examined in the whole subject of anatomy in the class B examination.

Students claiming exemption under the bye-law shall, on entering an affiliated veterinary school, submit to the Secretary of the Royal College of Veterinary Surgeons satisfactory evidence that they are entitled to such exemption.

Candidates possessing similar qualifications granted by Colonial or foreign licensing bodies, shall submit their certificates to the Examination Committee, who shall report to the Council on the eligibility of the applicant for exemption or otherwise.

Mr. GARNETT: In moving the adoption of the report, I would point out that it was specially referred back from the last Council meeting. I will read what occurred at the last Council meeting to put the members of the Council in full possession of the facts—"It was resolved to recommend the adoption of the following bye-laws, in accordance with resolution 17 of the meeting of Council, April 11th, 1913." Exception was taken to that resolution, and it was proposed by Sir John McFadyean, seconded by Mr. Wharam, and resolved—"That the report be referred back to the Committee with instructions that they shall so amend it as to give exemption to those graduates in Arts who have passed in the subjects of Biology and Chemistry." It has been before the Committee again, and they have drafted the new bye-law that I have read out to meet that instruction.

Mr. SUMNER: I second the motion.

Sir JOHN McFADYEAN: May I ask what is the reason for requiring students claiming exemption under this bye-law to give notice that they claim exemption at the time they enter an affiliated veterinary school.

Mr. GARNETT: The point was discussed by the Committee, and the majority thought it was more satisfactory that he should have definitely to settle whether he was exempt on entering the schools rather than three months previous to his going up for examination. It was generally conceded that his certificates would have been examined by the heads of the different veterinary schools, and if they were submitted at the beginning there was no more hardship on him than in doing so a few months previous to going up for examination.

Sir JOHN McFADYEAN: I should have thought it would have been just as well to bring such students into line with the ordinary students with reference to the submission of their educational certificates. They are not required to submit their educational certificates when they enter an affiliated school; they are required to submit them three months before they intend to present themselves for examination. I merely wanted to know what was the reason. It seems a quite unnecessary time.

Mr. GARNETT: It was discussed, and it was altered in that way.

The resolution for the adoption of the report of the Committee was then put and carried.

REPORT OF THE FITZWYGRAM PRIZE AWARD.

The SECRETARY: The marks obtained by the candidates eligible for the FitzWygram Prize have been submitted to the College auditors, and they certify as follows, that the first prize of £39 18s. 11d., should go to Mr. W. H. Dawes, Royal Veterinary College, 839 marks; and the second prize of £23 19s. 5d. to Mr. J. A. Ward, Royal Veterinary College, with 777 marks.

On the motion of Principal McCall, seconded by Mr. Lawson, the report was adopted, and the prizes awarded accordingly.

APPOINTMENT OF SECRETARIES OF BOARD OF EXAMINERS IN SCOTLAND, LIVERPOOL, AND DUBLIN.

The SECRETARY: As instructed, an advertisement was inserted asking for applications for the appointment of local Secretaries at the usual fees, and I have received applications from the present local Secretaries only, namely, Mr. Archibald Baird, Scotland; Mr. Blackhurst, Liverpool; and Mr. Finlay Kerr, Dublin.

Prof. METTAM: I move that the three local secretaries be re-elected.

Principal McCALL: I second that.

The resolution was carried unanimously.

NOTICE OF MOTION.

Mr. GARNETT: I beg to give notice that I will move at the next quarterly meeting an alteration of bye-law 53a which has just been passed by the Council. It will be suspended now for three months.

This concluded the business of the quarterly meeting of Council.

SPECIAL MEETING OF COUNCIL.

A special meeting of Council was held at the conclusion of the quarterly meeting, Mr. J. H. Carter, President, occupied the chair, and the same members were present as at the quarterly meeting.

The minutes of the last special meeting, which had been printed and circulated, were taken as read and confirmed.

MOTION BY MR. MULVEY.

Mr. MULVEY: I move in accordance with the motion of which I have given notice, "That the revised second Schedule, as amended by the Examination Syllabus Committee, be adopted." A copy has been supplied to each member of the Council.

Maj.-General THOMSON: I second that.

The resolution was carried unanimously.

MOTION BY PROF. METTAM.

Prof. METTAM: I beg to move, in accordance with the notice of motion I gave at the last meeting, "That the revised regulations for the Fellowship Diploma, as approved at the previous meeting, be adopted." These revised regulations were considered over a long period of time by a Committee which you appointed, and the regulations which they suggest were a unanimous finding. I move their adoption.

Principal McCALL: I second that.

Mr. TRIGGER: If this motion is going to be carried, what is the use of going into the question of the new Charter?

Prof. METTAM: These regulations cannot come into force unless the new Charter is obtained.

Mr. TRIGGER: All I want to be sure of is that it does not close the discussion on the Charter.

The PRESIDENT? It is subject of course to the Charter being granted.

The resolution was put and carried unanimously.

MOTION BY PROF. METTAM.

Prof. METTAM: In accordance with the motion of which I have given notice, and subject of course to the granting of the new Charter, I propose—"That the regulations for a new Diploma in Veterinary State Medicine, as approved at the previous meeting, be adopted." They will come into force at the time of the new Charter. The question of the granting of another Diploma than that of the Fellowship has been for some time before the profession and the Council, and the regulations as printed and circulated are the findings of your Committee. I move their adoption,

Maj.-General THOMSON: I second that.
The resolution was carried unanimously.

MOTION BY MR. MULVEY.

The following resolution stood on the agenda in the name of Mr. Mulvey—"Preliminary Examinations: That Schedule 1, as revised in accordance with the recommendations of the Preliminary Examination Committee, be adopted."

Mr. MULVEY: I am going to ask the leave of the Council to withdraw this proposal in reference to the Preliminary Examinations.

Mr. TRIGGER: I move that Mr. Mulvey be allowed to withdraw.

The resolution, granting Mr. Mulvey permission to withdraw, was seconded, and carried unanimously.

The PRESIDENT: That is the completion of the business to-day.

On the motion of Dr. McI. McCall, seconded by Mr. Packman, a hearty vote of thanks was accorded to the President for his conduct in the chair, which the President briefly acknowledged, and the meeting terminated.

The Royal College of Veterinary Surgeons v. Kennard.

This was heard in the Divisional Court of the High Court of Justice on Tuesday, 14th October, the Court consisting of Mr. Justice Ridley, Mr. Justice Scrutton, and Mr. Justice Bailhache.

Mr. Morton Smith (instructed by Messrs. George Thatcher and Son, solicitors to the Royal College of Veterinary Surgeons), appeared as counsel in support of the appellants, and Mr. Ralph Thomas appeared as counsel for the respondent.

Mr. Morton Smith said the case for the decision of the Court had been stated by four Justices of the Peace of the County Glamorgan, usually sitting for the Division of Kibbor. At the Court of Summary Jurisdiction, sitting at Llandaff, an information was preferred by the R.C.V.S. against the respondent for that he "not being on the Register of Veterinary Surgeons, and not holding at the time of the passing of the Veterinary Surgeons Act, 1881, the veterinary certificate of the Highland and Agricultural Society of Scotland, did, on the 13th December, 1912, at Horborne, Evansfield Road, in the parish of Llandaff, unlawfully take and use an addition and description, to wit, "Canine Surgery," thus stating that he was specially qualified to practise a branch of veterinary surgery contrary to Section 17 of the aforesaid Statute." The case was heard on the 10th February, 1913, when the Court dismissed the information and ordered the appellants to pay the sum of five guineas for costs. In compliance with an application from the appellants the Justices stated a case, from which it appeared that the respondent caused, or permitted to be exhibited over the entrance door to his premises a red glass lamp, on which were inscribed the following letters and words: "A. E. Kennard, Canine Surgery," and on the wall of the premises a brass plate bearing the inscription "Canine Surgery, A. E. Kennard." On the part of the appellants it was contended that the words "canine surgery" standing alone must imply either that a person duly qualified within the meaning of the said Act, or specially qualified to practise veterinary surgery would be found within the "surgery," or that coupled with the name of the respondent the words could only mean that the respondent was such a person. For the respondent it was contended that a fair and only reasonable construction of the words was that surgical treatment could be rendered on the premises by a per-

son therein, and that there was no statement as to any qualification at all, or description of the respondent as a specially qualified person. The attention of the Magistrates was particularly called on behalf of the respondent to the difference in the wording of Section 16 and 17 of the said Act, and to the omission from Section 17 (under which the information was expressly laid) of the words "or implying," which appear in the former section, and it was also contended that the description must be a personal one and not one applicable to a place. The attention of the Magistrates was called by the parties to the following cases: Royal College of Veterinary Surgeons *v.* Robinson, and Royal College of Veterinary Surgeons *v.* Collinson. The Magistrates also referred themselves to Attorney-General *v.* Churchill's Veterinary Sanatorium Limited, and the Royal College of Veterinary Surgeons *v.* Groves. Also to a case decided on the very similarly worded Section 3 of the Dentists Act, 1878, (which section, however, contains the word "implying," *Bellerby v. Heyworth*, the latter case having particular bearing on the personal application of the description. The Magistrates distinguished Robinson's case on the ground that in the descriptive words there complained of, namely, "J. Robinson, Veterinary Forge," the word "veterinary" is one of the particular words used in the said Act, and is also primarily and in its ordinary sense descriptive of a person and not of a place; and Collinson's case, and Churchill's case were decided on the ground that in each of these cases the descriptive words were wholly or partially personal, and that the word "specialist" appeared in such descriptive words in each case.

After considerable argument on behalf of both the appellants and the respondent, the Court delivered the following judgment:

JUDGMENT.

MR. JUSTICE RIDLEY: In this case the point raised is no doubt one of a difficult nature, in this sense, that the decisions run rather fine, and that it is difficult, perhaps, to reconcile all those that have been given upon the meaning of the Veterinary Surgeons Act, Sections 16 and 17, or, more strictly speaking Section 17, and the Dentists' Act. The magistrates in this particular case, after having considered the cases which were quoted before them, came to the conclusion that the words did not come within the provisions of the Section. Those words were as stated in the case: "A. E. Kennard, Canine Surgery" on a red glass lamp, and also upon the wall of the premises a brass plate bearing the inscription, "Canine Surgery, A. E. Kennard."

That being the state of things, it was contended that under Section 17 of the Veterinary Surgeons Act he had done a thing which came within the provisions of that Section and made himself liable to a fine not exceeding £20. The words of that Section so far as they are material are these: "If any person other than a person who is on the Register of Veterinary Surgeons takes or uses the title of veterinary surgeon or veterinary practitioner, or any name, title, addition or description, stating that he is a veterinary surgeon or a practitioner of veterinary surgery or of any branch thereof, or is specially qualified to practise the same, he shall be liable to a fine not exceeding twenty pounds."

The question for our decision is not without authority. Perhaps the first case that should be referred to is the Royal College of Veterinary Surgeons *v.* Robinson, in 1892, 1 K.B., where it was held that "Veterinary Forge" came within the Act of Parliament; that "Veterinary Forge" meant this—that the person who used the words was claiming for himself that he was a practitioner of veterinary surgery. That was in 1892.

In 1908 the case of the Royal College of Veterinary Surgeons *v.* Collinson came up for decision in the Divisional Court, and it was held that the words "Canine

Specialist, Dogs and Cats treated for all diseases," also came within this Section of the Act of Parliament. I was a member of that Court; the Lord Chief Justice and my brother Darling were the other two members. We, the Puisne judges, agreed with some hesitation with the judgment of the Lord Chief Justice, who had a decided opinion that the words "Canine Specialist, Dogs and Cats treated for all diseases" did claim, by the person who used them, that he was specially qualified to practise the treatment of the diseases of dogs, and therefore he came within the words in the Act of Parliament, and was liable to the penalty. We, on the other hand, had some doubts on the matter, but we agreed with the judgment of the Lord Chief Justice, and said that the words must be taken to imply that there was that skill, and that therefore it was proper to say the words were within the scope of the Act of Parliament.

If the case stood without any more recent decisions than that, what would be the position of the Court to-day? There are no such words here as "Canine Specialist"; there are the words which I have mentioned, "Canine Surgery, A. E. Kennard." If a man uses those words, does he do that which the Lord Chief Justice relied upon in giving his decision, and which we followed? Does he indicate that he is specially qualified to practise the art or the skill of a veterinary surgeon in treating the diseases of dogs? We should have had to argue that point, and to determine whether or no this case was distinguishable from that because the word was "Surgery" and not "Surgeon"; in other words, instead of being "Canine Specialist" and saying that the person who was practising there was a specialist in the diseases of dogs, the place itself or the place in which dogs are treated. I think it would have been a very arguable point, and I am not quite sure that I would not on my own view have thought that there was a distinction. The Act of Parliament says in this way—it is the person at whom it is directed. It says, "If any person takes or uses the title of veterinary surgeon or any name, title, addition, or description claiming that he is a veterinary surgeon," and we have to deal with the penalty clause; is it right to say "Yes," if it is his own personal skill that he is claiming to possess,—"he is within the Act of Parliament"—but to say that the place is used for a canine surgery is not? I do not know. I rather think I should have taken that view. It seems to me that the case of *Bellerby v. Heyworth* is very important upon this point. I think we have here the authority of the Court of Appeal, and particularly of Lord Justice Buckley, in saying that that is a good and substantial distinction. The judgment of Lord Justice Buckley *v.* Heyworth, 1909, 2 Chancery Division, reported at page 23, and the judgment at pages 30 to 33, rests a good deal upon the case of *Elmslie v. Paterson*, a Scotch case reported in 24 *Rettie*, and, whilst approving of that judgment, reasons out the distinctions I have just been suggesting. I do not think I need read much of that judgment, but it is the fact that it does rest upon the distinction which I have been mentioning. He says: "In reading those words it is to be observed that they are confined to forbidding descriptions of the person as distinguished from descriptions of the Acts to be done by the person. . . ." "I think that under this Act of Parliament any man may say that he does dental acts, but he must not, unless he is a qualified person, say he does them as a dentist;" and when we look at the next case of *Elmslie v. Paterson* we find that the words "American dentistry, Dental Office," were held not to be within the Dentists' Act. I am not able now to see the difference between this case and *Elmslie v. Paterson* in respect of this matter. There may be one or two words difference between the Dental Act and the Veterinary Surgeons Act, and indeed there are, as has been pointed out by Mr. Morton Smith, but for this pur-

pose I am not able to distinguish them. If "American Dentistry" and "Dental Office" do not mean that the person was taking upon himself the name, title, or addition, or that he had a special qualification, I do not quite see how "Canine Surgery" can. "Canine Surgery" is a description of the place and not of the man. A man is forbidden to call himself certain things. He must not call himself a dentist, but it does not follow that he is not to put up that he has got a surgery. People may say—and I have no doubt they will say—"This is rather a fine distinction." I think it is a fine distinction, but it has the authority as I make out, of the Court of Appeal in that case, and it would be as it seems to me rather unfortunate if we were to take upon ourselves to-day to say that we did not agree with it. It remains therefore according to that decision of *Bellerby v. Heyworth* that there is a distinction to be drawn here between the case before us and that of the Royal College of Veterinary Surgeons *v. Collinson*. In the *Collinson* case, the man said he was a canine specialist. In this case the man has not said that he is a canine specialist. What he has said is equivalent to what was said in the Scotch case, "American dentistry" and "Dental Office" in that he has merely put up "Canine Surgery, A. E. Kennard." For this reason, therefore, though with some hesitation, owing to the nicety of the decisions, I think the magistrates were right. There is this further also to be said, and it is possible that this also has a good deal of bearing upon the subject, that the decision in *Bellerby v. Heyworth* to this effect, that the words "Specially qualified to practise the same" in Section 3 of the Dentists' Act, being applied to Section 17 of the Veterinary Surgeons' Act, come to this, that the description against which the Act is directed means something specially descriptive of the fact that he claims to be a veterinary surgeon, and does not apply to skill. That would somewhat still further narrow the effect of Section 17, because it would from that decision follow that the words which are relied upon as being a breach of the Act must have a special relation to the qualification of the person who uses them as a member of the Society in question, and not as to the particular skill which he may happen to possess. That, however, is not the reason upon which I prefer to rest my decision in this case. For these reasons I think the magistrates were right in their decision.

MR. JUSTICE SCRUTTON: A. E. Kennard put on a red lamp over his door the words "A. E. Kennard, Canine Surgery." Thereupon the Royal College of Veterinary Surgeons summoned him for "Taking or using the title of veterinary surgeon or any name, title, addition or description stating that he is a veterinary surgeon or a practitioner of veterinary surgery or any branch thereof or is specially qualified to practise the same." The magistrates dismissed the information. I have, after some hesitation, come to the same opinion as my lord that magistrates were right. I am not certain that it is very profitable to give a judgment of any length, because the only result will be that some other ingenious unregistered practitioner will appear with a new form of words which he thinks he has extracted from some sentence in the judgment of one of the members of the Court; but as I think I have arrived at a principle satisfactory to myself as to how this Statute should be construed, and as I have gone through the authorities, I propose to state shortly the result of my consideration.

The Royal College of Veterinary Surgeons appears to have two registers, one of veterinary surgeons who have been passed on examination; one of existing practitioners who have not passed on examination but who have for five years before the passing of the Act practised veterinary surgery. Section 16 of the Act forbids any person who is not a Fellow or a Member taking any name, title, addition, or description stating or

implying that he is a Fellow or a Member. That comes into effect on the passing of the Act in 1881. Section 17 comes into operation two years later, for some reason, and prohibits people not on the register from taking or using "the title of veterinary surgeon or veterinary practitioner, or any name, title, addition or description stating that he is a veterinary surgeon or a practitioner of veterinary surgery, or of any branch thereof, or is specially qualified to practise the same." I think that must go further than Section 16. It comes into operation at a different time, and I do not think therefore, "veterinary surgeon" or "practitioner" can be limited to statements that the man is on the two existing registers. I think Mr. Morton Smith is right in saying that is dealt with by Section 16.

Then comes the question, What is the offence larger than Section 16, or different from Section 16, which a man commits by taking the name, title, addition, or description as stated, or the statement that he is specially qualified to practise? Now the first thing I notice is this: it is not an offence to perform a veterinary operation. The only result of not being on the Register of the Royal College of Veterinary Surgeons is that you cannot recover a fee for performing it, a difficulty which you get over by taking cash in advance. If you are allowed to perform an operation it would be very curious if the Statute has prevented you from saying that you are ready to do it. It would be very curious if a Statute has made it an offence to say that you will do a thing which by law you are entitled to do. I should, therefore, approach the Section with a feeling that it is improbable that a man is prohibited from saying that he is ready to perform an operation when by law he may perform such an operation but may not recover fees for it.

The authorities stand in this way, shortly. In 1892 a Divisional Court held that the words "veterinary forge" implied special qualifications to practise a branch of veterinary surgery. In 1908, in *Collinson's* case, all three Judges of the Divisional Court said they would have decided the *Robinson* case the other way; and two of them said they would have decided the *Collinson* case the other way, but for the fact that the President of the Court took the opposite view and, with hesitation, they followed him. The words in *Collinson's* case were "Canine specialist, dogs and cats treated for all diseases." There can be no doubt that that is a personal description of the man who puts it up. He is a specialist, and I can quite understand the Court saying that a man who says he is a specialist says he is specially qualified to practise. He does not merely say, "I am ready to practise," he says, "I am a specialist, I am specially qualified to practise." At that time Lord Alverstone no doubt took the view that "specially qualified" was not limited to the qualifications necessary to be registered, but in the popular sense meant qualifications of skill other than the mere fact of registration. A year afterwards, Lord Alverstone was the presiding Judge in *Barnes v. Brown* under the Dentists' Act. *Barnes* had said: "Finest artificial teeth at moderate prices. Extractions, advice free, painless extractions," and Lord Alverstone, citing in support of his view *Robinson's* case and *Collinson's* case, held that "specially qualified" was not limited to registration under the Statute, but extended to the popular meaning of "specially qualified." The next year that case came under the review of the Court of Appeal in *Bellerby v. Heyworth*, and the Court of Appeal, acting on the principle that I have endeavoured to state—that it is extremely improbable that Parliament can have intended to punish a man for saying that he will perform an operation which he has a legal right to perform—declined to follow the judgment in *Barnes v. Brown*; declined to say that a statement of special qualification was implied in a statement that a man could do work,

and the Master of the Rolls adopted the language of the Scotch case in *Elmslie v. Paterson*: "If the appellant can without any breach of the criminal law extract teeth and put in false teeth, or the like, I can see nothing in the Statute forbidding him from announcing that he does so, which is just announcing that he practises dentistry. . . . It is needless to say that I have considered what was said by the Lord Chief Justice and Bigham J. in that case with the utmost respect, but I must confess that I am unable to follow the reasoning in that case—reasoning which seems to me to go the length of saying that people must not announce that they do that which by law they are entitled to do, and that by saying that they do, and do well, that which the law entitles them to do they are necessarily infringing the Act. I can find no personal description, either expressed or implied, in what has been done here as brings the case within the section."

That being the decision of the Court of Appeal, the case was taken to the House of Lords, and the House of Lords in 1910 affirmed the decision of the Court of Appeal, over-ruled the decision in *Barnes v. Brown*, which had proceeded on the decision in *Collinson's case*, and held that the words "specially qualified to practise dentistry" in the Dentists' Act were limited to the possession of qualifications for registration.

In view of what has been pointed out by Mr. Morton Smith, and the fact that there are two Sections in the Veterinary Act and one Section in the Dentists' Act, I do not think it is necessary to say that the words 'specially qualified' in Section 17 of the Veterinary Act are limited to qualifications for registration. But in view of the reasoning of the Court of Appeal and of the

House of Lords overruling the decision in *Barnes v. Brown*, I do think that to get an offence under Section 17 you must find more than a mere statement that the man is ready to do what by law he is entitled to do. You must find some statement that he is specially personally qualified to undertake the work—not merely ready to do it, but specially personally qualified to undertake it. Now do I find such a statement in the words "Canine Surgery"? They appear to me to amount to nothing more than a statement: "Here is a place where surgical operations will be performed on dogs." A man may perform surgical operations there. It will be no offence under the Statute if he does perform a surgical operation there, but he must not say he is specially qualified to do so. Does he say he is specially qualified to do so by saying he is ready to do so? I take it the reasoning in the Court of Appeal and the House of Lords, and in the Scotch case, too, bind me to say—although I quite agree with it without being bound—that that statement is not a statement of special qualification, but is a statement of readiness to do what by law he is entitled to do. For these reasons I think the Magistrates were right in holding that in this case there was no offence shown under the Statute.

Mr. JUSTICE BAILHACHE: I am of the same opinion. I think the net result of all the cases is this, that it is no offence to say, "I have a canine surgery," though it probably remains an offence to say, "I am a canine surgeon." I therefore agree with the judgments which have already been given.

Mr. Thomas: My lord, the appeal will be dismissed with costs?

Mr. Justice Ridley: Yes.

A New Internal Secretion Gland.

Pende (*Rif. Med.*, May 31st, 1913) describes an organic structure having the character of an internal secretion gland, and situated near and in connection with the thyroid, parathyroid, and thymus, especially with the superior parathyroid and with the superior pole of the thymic lobes. The new gland is found constantly in the human fetus from the fifth month, and persists for about a year after birth; it has also been found in the dog. It is highly vascular, and consists of some fifteen to twenty lobules of epithelial character; the individual cells are rich in lipid content, and in some cases showed evidence of karyokinesis, pointing to the fact that the gland is functionally active. The author says it can easily be differentiated from aberrant sections of thymus gland, and in cases where his new gland and outlying pieces of thymus coexisted there was no difficulty in making out which was new gland and which thymus. In size the new gland exceeds the parathyroid tissue. As his is only a preliminary communication, dealing mainly with the morphology, the author promises further details as to function, etc., when his researches are more advanced.—*B.M.J.*

Milking Cows.

With the growth of the milk trade in this country the "running dairy" (i.e., one in which cows are coming into milk all the year round) has become fairly common, and more especially in the case of farms that breed their own heifers. Still, the trade in incoming cows is far heavier in the spring than at any other period of the year, although in recent years the more profitable autumn and early winter coming-in cow has grown to a big business. Experiments and researches have been going on for many years at the Vermont and other American stations. All the experiments tended to show that autumn cows "hold out" longer than those that come on in the spring, and, as a rule, give larger yields. There is also less variation in the quality of the milk. The cow that comes on in the spring rapidly increases the fat content of her milk, beginning about five months after calving; while the autumn cow maintains fairly even quality throughout lactation, seldom improving the fat content more than $\frac{1}{2}$ to 1 per cent. The solids-not-fat content is most uniform month by month in the milk from the autumn cow, while that from the milk of spring cows lessens somewhat in the summer time.—*L. S. J.*

The "Completest Horse."

"QUIET SHOOTING HORSE.—To be SOLD, one of the completest HORSES in this kingdom, to carry any infirm timid Gentleman; he is a very handsome Gelding, six years old; he is one of the safest and best walkers in this kingdom, can trot twelve miles an hour, a delightful canter, and is, without exception, one of the safest and pleasantest little horses to ride that can possibly be; he is not apt to shy, or make a false step, and you may fire over him; perfectly sound, free from vice or blemish, and a trial granted. He is the property of a Gentleman immediately going abroad, or would not on any account be parted with. Enquire for William, the Ostler, at the General Wolfe livery-yard, Oxford Street, opposite Park Lane. This horse is worthy the attention of any heavy timid Gentleman, in want of a safe, quiet, handsome little horse; colour dark brown, not any white about him. The lowest price 37 guineas, which is a great deal less than his real value."—From *The Times* of 100 years ago.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Oct. 14.

REGULAR FORCES. ARMY VETERINARY CORPS.

Col. A. F. Appleton is placed on the half-pay list. Dated Oct. 15.

Lieut.-Col. J. Moore, A.V.C., to be Colonel, *vice* A. F. Appleton. Dated Oct. 15.

Personal.

Mr. HUNTING's condition has not improved during the week, and a surgical operation has been decided upon.

Mr. and Miss HUNTING desire to thank many friends for sympathetic enquiries and letters, to which it has not been possible to reply individually.

MARTIN—SAMUELSON.—On the 9th Oct., at St. Mary Abbots, Kensington, Major Ernest Edmund Martin, A.V.C., son of the late T. J. Martin, of Taunton, and Alexine Aimée, youngest daughter of the late Alexander Samuelson, of Kensington.

Mr. JAMES LINDSAY, M.R.C.V.S., was unanimously appointed Veterinary Inspector for the Burgh of Dumfries by the Town Council at their last monthly meeting.

OBITUARY

JOHN THOMSON, M.R.C.V.S., Coventry.

Graduated, Glas: Dec., 1874.

We regret to have to record the death of Councillor J. Thomson, M.R.C.V.S., which occurred about mid-day on Sunday last at his residence, 2 St. Patrick's Road, Coventry, after a very brief illness, the cause of death being arterio sclerosis. He was 61 years of age, and leaves a widow, but no family.

Mr. Thomson was a native of Perthshire. He was very successful as a student, and came to Coventry about thirty years ago, and became widely known throughout Warwickshire and the Midland Counties as a skilful veterinary surgeon. He had stables in Much Park Street.

The deceased gentleman was a member of the Coventry City Council, having been first elected in July, 1904, as a representative of Cheylesmore Ward, and he had sat continuously since then. He was Vice-Chairman of the Sewage Farm Committee, on which committee his practical knowledge of horses and stock and of farming proved of the greatest value. Mr. Thomson was an earnest and conscientious worker, though he seldom spoke in public, and was greatly esteemed by his colleagues. In politics he was a staunch Conservative, and as a churchman attended St. Michael's Collegiate Church. He was a member of the Coventry Education Committee, and one of the managers of St. Michael's Schools. He was a vice-president of the Caledonian Society for Coventry and District, and had always taken an active interest in its work.—*Daily Telegraph* (Coventry).

EPHEMERAL LAMENESSES.

Sir,

I feel certain all of your readers are thankful to Mr. E. Wallis Hoare for the lucid exposition of his views on my remarks on ephemeral lamenesses. For my own part I congratulate him heartily, and with the exception of the paragraph marked "3" I do not see occasion to offer any criticism to his reply.

Mr. Hoare says he is well aware that in the early stage of navicular disease a very careful examination of the navicular bone is necessary in order to detect the lesions. In reply to this, I ask him how often does one get the

chance or deem it advisable to make a post-mortem examination in the early stage of navicular disease?

One may often get the opportunity of making a post-mortem and finding advanced lesions within a short period of the first appearance of lameness. The interpretation of these facts is that in such cases the disease must have been progressing long before the evidence of lameness. Opposite to these facts, we may witness chronic lameness with no well marked lesions.

Mr. Hoare further says he is very sceptical as to the possibility of a horse affected with navicular disease being able to go sound for any length of time, and believes that such is difficult to prove.

Notwithstanding Mr. Hoare's rather pronounced views on the question, such cases do occur, and are not difficult to prove. A post-mortem examination after following the career of an animal showing freedom from lameness for long periods is not always impossible, even if one have to wait two or three years.

In a great number of cases of foot lameness in light bred horses, without a post-mortem examination, diagnosis is merely conjecture on probabilities. In bilateral intramural sidebones—an inflammatory condition with calcification of the lower half of the lateral cartilages—in light bred horses, the characters of the lameness are identical with those of navicular disease. In the former, however, the young adult horse is generally the victim, whereas in the latter it is usually the aged adult. As they both respond to the same treatment, a differential diagnosis is not of much practical importance. This form of sidebone does not, as a rule, progress, even after neurectomy.

After all, what does it matter whether one calls navicular disease, rheumatic lameness or navicular disease. One cannot prove it one way or the other without a post-mortem examination. As to treatment, one is limited in range—fire, blister, unnerve, rest, form the therapeutics of the average veterinary surgeon. Others, wiser than most, put salt on the tail.

I was once called to see a cob that had been lame for two years, in spite of the skill and care of two eminent men in the profession now deceased. The morning I saw the cob it was, unfortunately for me, sound, and remained so for twelve years, when it fell dead from heart disease. If I had seen it a day sooner, when it was lame, and had prescribed the application of salt to the tail, I would have, without a shadow of doubt, got great credit for touching the spot. As it was, I did get credit for charming away the lameness.

Other cases I have encountered in which horses have been seized with severe lameness when at work and had to be brought home in a float. After a few hours rest the lameness has disappeared, to reappear at irregular intervals at work. In some I have never observed the animal when lame, because the lameness had disappeared before my visit. The lameness eventually did not reappear. What are such cases? They could not be of an embolic nature, because the lameness suddenly appeared at irregular intervals. Judging from one's own feelings, these cases resemble the ephemeral rheumatic attacks when one puts one's limbs or muscles in an unusual position, especially after some previous exertion to which one has not been accustomed.

ANTI-HUMBUG.

DIAGNOSIS.

Dear Sir,

In writing articles for publication it is usual to use the plural "we" instead of the egotistical "I," but although this should be appreciated as a general rule, yet in some cases it is most objectionable, as for instance—

An individual conceives an idea, or is impressed from his experience that so-and-so is a fact. He should not definitely state in a public communication that from "our experience"—that is, the experience of the members of the profession to which he belongs; or "we" know that such-and-such is a fact, especially if the fact is that from the individual's experience in making post-mortem examinations he has found that his diagnosis usually proved to be incorrect. Of course, if he pleases to stultify himself by publishing his

errors he is quite at liberty to do so, but, in my opinion, he has no right to use the word "we," or in any other manner to inculcate the entire profession by including it by using the plural instead of the singular case in publishing his deplorable experiences; nor has he any right to stigmatise those whose experience is otherwise to his as "Sir Oracles etc." or to write in a derogatory manner of them. Such conduct, to my mind, is a breach of professional etiquette, and certainly does not tend to inspire the public with confidence in the ability of the members of the profession to apply practically the knowledge which is set forth as taught in the curriculum of our Colleges. Unfortunately, as above stated, some are lacking of the ability to utilise it successfully, but in the manner as above described are pleased to thrust their ability, or inability, forward in such matters as representing that of the whole body of their fellow practitioners.

The most intimate knowledge of anatomy, physiology, and bacteriology, etc., is not sufficient for a diagnostician; he also should be a close observer, having a clear perception of how to obtain information, such as the "history of the case" etc., requisite in forming correct opinions in differentiating ailments, and be able to apply intelligently the knowledge obtainable from the above-named subjects. His senses should not be defective, as it would be impossible for one musically deaf to discern correctly the difference of sounds, and a person colour-blind could not be expected to notice changes of colour of tissue, etc., and in a like manner, if the olfactory organs are defective, the power of noticing peculiar odours would not be reliable. The sense of feeling should be keen, otherwise a practitioner would often fail to discover important, though minute, changes of tissue, etc. Added to these, a careful examination is indispensable in making a correct diagnosis.

Of course, there are obscure cases—cases exhibiting indefinite symptoms, upon which a definite opinion should not be formed, but if such symptoms are exhibited as to justify a practitioner in forming a definite opinion, surely the post-mortem should verify the correctness of the opinion—not prove his diagnosis to be incorrect.

JAS. McKENNY, M.R.C.V.S.

REBATE ON PETROL.

Sir,

Now that such an extraordinary amount of travelling has been thrown upon us by the new Tuberculosis Order—especially as proper provision has not been made to compensate us for our arduous duties, it strikes me that the Government could hardly refuse us the rebate in petrol which they have granted to the medical profession, for are we not working for the eradication of human consumption. I think that all our Societies should move in this matter at once.

Before concluding, kindly permit me to state how sorry I am to see by your issue of to-day that our esteemed friend Mr W. Hunting, is so unwell. Every member who knows his great worth will earnestly pray that he may be quickly restored to health,—Yours truly,

JOHN HOLLAND.

Athy, Oct. 11.

AMPUTATION OF COW'S LIMB.

Sir,

I was interested to read in your issue of the 11th inst. of the successful operation carried out by Mr. Peter Meikle, M.R.C.V.S., and I am sure it will also interest your many readers to know that the paragraph and identical photograph appeared in *The Glasgow Evening Times* about three weeks ago.—Yours truly,

AMPUTATION.

Original articles and reports should be written on one side of the paper only and authenticated by the names and addresses of writers, not necessarily for publication.

No. 1320.

OCTOBER 25, 1913.

VOL. XXVI.

OPERATIONS WITHOUT CASTING.

Many of us can remember the days when a horse destined to a serious operation, whether to be done under anaesthesia or not, was invariably first cast with ropes or hobbles. Probably more operations are performed now than then; but the hobbles or ropes are not so obligatory. A variety of substitutes for them have appeared.

Of course, operating tables for horses are available to those who can afford them; and in many respects they seem preferable to casting; but their use will always be rather restricted. A much more important substitute for casting, to the average practitioner, has come from the comparatively recent development of local anaesthesia. Many operations which were impossible without casting twenty years ago can now be performed painlessly upon the standing horse by modern methods of local anaesthesia. Again, the possibility of chloroforming the horse standing has become recognised; and an increasing number of veterinarians—like Mr. P. J. Howard, whose paper upon the subject appears in our pages this week—now dispense with casting in this manner. Another somewhat similar method, much practised abroad though not here, is the administration of large doses of chloral hydrate, generally given rectally.

Not one of these methods is likely to altogether displace casting. But alternatively they will supersede it to a considerable extent, and the change will be for the better.

There are two real objections to hobbles and casting ropes. Their use demands assistance, which ought to be skilled; and it is often difficult to obtain this in practice. Most clinicians can recall some trying experiences of casting with unskilled and nervous assistants. Again, though accidents to the horse in casting are not common, they are generally mortal when they do occur, and it seems impossible to guard against them with certainty. Casting by hobbles or ropes cannot be called easy unless skilled assistance is available, and under no circumstances can it be called quite safe; yet the method will always be necessary in given conditions, especially in emergencies in country practice. But their disadvantages should be remembered, and all available substitutes for them studied. The ideal practical clinician would be adept at several methods of casting, and would also understand the modern methods of avoiding casting. Local anaesthesia seems the most important of these, and "chloroform standing" may ultimately not be far behind it. Both require knowledge and practice for their proper performance.

INTUSSUSCEPTION OF THE CÆCUM IN A HORSE.

The patient, a seven-year-old black gelding, was admitted to the hospital at 3 p.m. on August 8th, 1913, showing symptoms of subacute abdominal pain, temperature 102, visible mucous membranes slightly congested, pulse 60, respirations accelerated. Enemata were administered, and the following drench given;—

R Ol. lini. Oi.
Ol. terebinth ʒi.

At 5 p.m. the animal still exhibited symptoms of pain, and a bolus consisting of Chloral hydrate ʒi. was given.

At 8 p.m. the patient was showing symptoms of exhaustion, and the following was prescribed:—

R Spts. ammon aromat. ʒiss.
Spts. æther nit. ʒiss.
Aqua ad Oi.

At 10 p.m. the animal being still in pain one ounce of Chloral hydrate was again administered.

At 3 a.m. the drench given at 8 p.m. was repeated.

Between 3 a.m. and 4 a.m. the patient became very violent, plunging and striking out with his fore feet; consequently a third ounce of Chloral hydrate was given.

At 5 a.m. exhaustion was very marked, and the patient died at 8 a.m.

Post-mortem examination revealed intussusception of the cæcum, and a rupture of the cæcum about two inches in length, close to the ileo-cæcal valve. The cæcum had passed into the lumen of the double colon, being turned completely inside out, like the finger of a glove.

The cæcum was strangulated at the caput cæci, the strangulated gut being of a deep red colour. The walls were fully an inch in thickness, due to a yellowish-red gelatinous infiltration into the connective tissue between the mucous membrane and the muscular fibres of the organ.

The entire intestines showed evidence of enteritis in an early stage, with patchy, ecchymosed areas throughout the lining mucous membrane. In the walls of the intestines were embedded numerous sclerostomes.

After carefully considering the case, I came to the following conclusion regarding the lesions found on post-mortem examination. The presence of the sclerostomes in the walls of the cæcum probably set up an acute inflammation, causing abnormal peristalsis, resulting in intussusception of the organ.

That the animal's death was brought about by this intussusception within seventeen hours from the first appearance of symptoms seems very improbable, and I am inclined to consider that the marked lesions found in the walls of the cæcum, and to a lesser degree throughout the whole intestinal tract, were the result of an acute intoxication, probably due to some of the common intestinal flora assuming pathogenic properties.

S. BLACK, Capt. A.V.C.
Aldershot, October, 1913.

LANCASHIRE VETERINARY MEDICAL ASSOCIATION.

The quarterly meeting was held on Thursday, September 4th, at the Grand Hotel, Manchester, the President, G. H. Locke, Esq., in the chair. The attendance included Messrs. Stent, Price, Burndred, Hopkin, Wolstenholme, Taylor, Carter, Edwards, Garnett, Noel Pillers, Lloyd, Holroyd, Ferguson, and Brittlebank.

Visitors: Messrs. W. Atkinson, S. E. Holmes, and E. J. Burndred.

Apologies for absence were received from Messrs. Darwell, Abson, and Heyes.

Minutes.—On the proposition of Mr. Wolstenholme, seconded by Mr. Lloyd, the minutes of the last meeting were taken as read.

The PRESIDENT, before opening the proceedings, desired to offer hearty congratulations to Mr. Carter on his election as President of the Royal College of Veterinary Surgeons. They had always considered Mr. Carter to be a typical Lancashire member who had always looked after their professional interests in the north.

Mr. CARTER returned thanks for their congratulations on the distinction conferred upon him. He hoped he would have health and strength to enable him to carry out the duties pertaining to the position, not only with credit to himself but to the profession also.

Nominations. Mr. J. D. RANKIN, Colne, was nominated for membership by Mr. Brittlebank.

Elections. Mr. J. T. ABELL, Derby; Mr. E. J. BURNDRED, Blackburn; Mr. J. HUGHES, Welshpool; and Mr. A. M. MUNRO, Board of Agriculture, were unanimously elected members of the Association, being proposed by Messrs. Locke, Lloyd, Hughes, and Locke respectively, and each seconded by Mr. Brittlebank.

National Veterinary Benevolent and Mutual Defence Society: Election of Life Governor. Mr. BRITTLEBANK, secretary, reminded the members that this matter had been referred to the Council for consideration. They had met on August 13th, and recommended that Mr. G. H. Locke should be appointed.

Mr. TAYLOR had pleasure in moving that Mr. Locke be appointed to replace Mr. Faulkner as Life Governor of the Society; Mr. Wolstenholme seconded, and it was carried.

Mr. LOCKE accepted the honour with many thanks.

Election of Auditor. For the vacancy created by the death of Mr. Faulkner, the Council recommended that Mr. James Spreull be elected. This was proposed by Mr. Brittlebank and seconded by Mr. Noel Pillers. [Carried.]

New Tooth Shears. Mr. TAYLOR enquired whether anything had been done in this matter.

Mr. BRITTLEBANK replied that he was in communication with makers, and no doubt would be in possession of tooth shears within the next few days.

International Veterinary Congress. Mr. GARNETT asked what the Council recommended with regard to

the Congress. They were several hundred pounds short, and he thought the Society might consider whether they could afford an increased subscription.

Mr. BRITTLEBANK replied that the matter had been fully discussed, and he thought they had fairly good reasons for delaying the steps they proposed to take. In a short time, however, a circular would be sent to all members of the Lancashire V.M.A., and also to all members of the profession resident within fifty miles of Manchester, with the exception of Yorkshire. It was hoped that such a sum would be raised as would come up to what the Lancashire Society usually does.

Mr. STENT, as Treasurer, said it would be impossible to give a further sum this year out of the funds of the Association.

PATHOLOGICAL SPECIMENS.

Mr. A. W. NOËL PILLERS exhibited the following interesting specimens:—

1. *Ascaris transfuga* from a brown bear.

2. *Hypoderma* sp. Larval form from the spleen of an ox, found by Mr. E. J. Burndred, M.R.C.V.S., Blackburn.

3. *Linguatula lanceolata* usually known as *L. Tenioides*, from the nose of a dog, which formed the subject of a note in *The Veterinary Record* for July 26, by Mr. H. Tudor Hughes, B.Sc., M.R.C.V.S., Oswestry, by whom it was presented.

4. *Limnatis* sp. A leech from the nasal cavity of a dog from the Punjab of India. Presented by Lieut. Murray, A.V.C.

Mr. STENT submitted an X-ray photograph showing a tumour in the abdomen of a dog and gave the following history. "The animal was only five years old, but in a very obese condition, had always been healthy. It was taken suddenly ill with vomiting, and being a dog that rambled the owner thought it had taken up poison, and gave castor oil, which was immediately rejected. The sickness continuing I was called in, and finding much pain on abdominal pressure applied hot poultices and gave gastric sedatives, also glycerine enema, which soon acted, and gave some relief. There being no improvement next day, I suspected either intussusception or stoppage due to stones or bones. Finding it impossible correctly to diagnose which, owing to the very obese condition, I sought the aid of the X-rays, which revealed on the plate from which this photo was developed, what was apparently a large growth, by its size and shape; it certainly was not a stone, nor an intussusception.

Operation was attempted, but on opening the abdomen a large fibrous tumour was seen involving the bowels to such an extent that the animal was destroyed.

The points of interest are the use of the X-rays as means of diagnosis in abdominal trouble, and the fact of this large growth, weighing 8 ounces, not causing any trouble until acute symptoms such as might occur in ordinary gastritis, supervened: evidently brought about by pressure of the tumour on the bowels, causing complete obstruction.

Mr. BURNDRED mentioned a similar case in a cat, but the bowels were reduced externally about one-third their ordinary size and inside nothing could possibly pass.

Mr. WOLSTENHOLME exhibited the brain of a horse, which had been hardened and sectioned. The animal had died in the street from an attack of "Megrims." He had been struck with the paucity of lesions found on post-mortem in brain affections in the lower animals. At one time he had interested himself in examining the brain of cows which had died of milk fever, and also had the help of friends, but no change could be discovered. Then again, in examining the brain of horses affected with megrims he had never found more than congested vessels, except in one case, where hemorrhage had caused apoplexy.

The patient from which the specimen was taken was a cart horse, nine years old, which had been four years in the service of one company. No report or complaint had been made until about a month before death, and contrary to his wishes the horse was not sent to hospital, but remained at work, and died in the street. Congested vessels only were found.

Mr. Wolstenholme next showed the viscera from a fox terrier bitch; most of the organs of the body, showing firm, grey new growths, much like sarcoma. On microscopical examination they proved to be tubercle.

Also a portion of a tumour involving the small bowel of a cart horse. The patient was old, and commenced to lose weight without visible cause: after the lapse of a little time under rest and mild tonics, Mr. Wolstenholme explored the rectum and felt a tumour near the floor of the abdomen, at the full extent of his arm.

The horse was destroyed, and on post-mortem examination, two tumours were found, each about the size of a child's head; the small bowel passed through both of them, one was about six feet from the pylorus, and the other about twenty feet. A section under the microscope showed the bowel to be invaded by a new growth, like a small round-celled sarcoma, the muscular coat being mainly involved, whilst the mucous membrane was necrotic. No other growths were found in the body.

The action of the bowels had been normal and regular up to death. There was some colic after rectal examination.

Mr. Wolstenholme also exhibited dried plants of the *Cicer Arietinum* (Gram), and the *Lathyrus sativus* (Mutter), together with samples of the grain from each.

SOME INTERESTING CASES MET WITH IN GENERAL PRACTICE.

By W. GEO. BURDRED, M.R.C.V.S.

Mr. President and Gentlemen,—When our Secretary honoured me by asking me to read a paper before you, I had no hesitation in promising to do so, and I did not, until afterwards, realise that the time at my disposal was strictly limited and very inadequate. However, I have decided to bring to your notice a very few cases which present points of interest and should lead to a varied discussion. I shall not attempt to go into the extreme detail of each case, but shall give rather an impressionist account of each one as it presented itself to me.

Case No. 1.—On January 27th of last year, I was called to a grey cart gelding which was said to have gone suddenly lame, and on arrival at the stable found the said gelding resting the near fore-leg and exhibiting symptoms of very great pain. Attempts to make the animal move proved futile, and as the position of the limb gave me no definite sign at that time, I decided to have the shoe removed and the foot examined. Finding the result negative, I made a more thorough examination of the limb, and finally concluded that the pain was located somewhere in the region of the elbow joint. A dose of physic was given, and a stimulating liniment applied after hot fomentation.

The animal continued in the same condition for ten days, and then a doughy swelling appeared over the ulna. I suspected fracture, and placed the animal in slings. Consultation with a neighbouring practitioner rather strengthened this diagnosis, but it was decided to treat for a time and await developments, the treatment at this time consisting of the application of a 1 to 8 iodine ointment. Strange to say the swelling was much reduced by this, but as no improvement was apparent, the animal was destroyed on February 27th, just a month from the first sign of lameness.

Post-mortem. The affected leg was first examined. The intra-muscular tissue was infiltrated with a yellow

fluid and the muscle tissue was paler than normal. On opening the joint a large quantity of synovia escaped, and this when manipulated was found to contain grit, the result of erosion of the articular surface of the ulna, radius, and humerus. A further examination of the carcass showed, as far as the eye could see, the organs to be healthy, but there were numerous swellings along the course of the spinal vertebrae.

These swellings varied in size from that of a walnut to that of a cricket ball, or even larger. The knacker man was instructed to cut out these parts and send them to me, but, unfortunately, he first boiled them, so that the lesions don't exist completely in the specimen bones on the table.

The previous history of this horse may have some bearing on the case. He was bought from a dealer in 1910, and was passed as sound. About six months after purchase the membrana nictitans of the left eye was found to be enlarged and covered with small yellow specks, and the membrane was removed with satisfactory result, the animal keeping in apparently good health until about a year before his death. At that time he was noticed to be very unsteady when made to move in the stall, and finally fell, but got on his feet again very quickly. I saw him within two hours of this, and apart from the unsteady gait and a stiffness of the hind quarters, there were no definite signs from which to form a decided diagnosis. Treatment consisted of dieting and a dose of aloes, and he was fit for work in a few days. Latterly, however, his driver informed me that although he could back a heavy load well, he did not shaft comfortably down hill.

On no occasion was this horse's temperature more than 101 F. In the absence of a scientific examination of the lesions, I can only say that the whole facts suggest to me "tuberculosis," and I shall welcome discussion of this case in particular.

Case No. 2. The subject of this case was a brown cart gelding, about 12 years old, and over 18 hands high, the property of a contractor who owned about fifty horses.

History. Was bought from dealers in March, and was said to have come from Nottingham, and was a splendid draught horse. About the beginning of July it was not doing well, and the teeth were rasped at the request of the owner. Nothing further was heard of it until August, when the owner sent for a "purging ball," and the day afterwards called in veterinary aid. On this day the attending surgeon suspected glanders, and asked me to see the case. I went over with him, and we examined the horse together.

Symptoms. The temperature was 105 F., appetite capricious, coat staring, mucous membranes pale and unhealthy, and when made to move the animal groaned. The hind legs were very much swollen, and on the course of the lymphatics were numerous hard swellings, varying in size from half a walnut to a filbert. Several of these swellings had burst and formed ulcers. There were also swellings on the abdomen and breast. The lymphatics in the inter-maxillary space and on the side of the cheeks were enormously swollen, knotted, hard, and adhering to the surrounding tissue. Ulcers were present in this locality, discharging a viscid straw-coloured fluid, and there were bare patches, apparently where ulcers had healed. When these swellings were first noticed, the man informed us that he had been fomenting them, and had got them to burst. There was a discharge from both nostrils, but more particularly the right, and ulcers and pimples were easily seen on the schneiderian membrane.

Diagnosis. Glanders and farcy. The interesting part of the case lies first in the fact that the disease had so far advanced before it was recognised.

Next that although the matter was immediately reported to the authorities no action was taken until

the next morning, when the local veterinary inspector arrived and confirmed our diagnosis. The police then took charge, and the carcass was buried in the contractor's yard in a hole eight feet deep, after covering it with quicklime, within a few yards of the stables, and not more than fifty yards from the main road of a fairly thickly populated town. The remaining horses were not tested with mallein, and work went on as usual.

About the time this animal was bought, I was asked by the police to inspect the horses on the premises of the dealers from whom the horse was bought, as an outbreak in another Midland town had been traced to this stable, but no horses were on the premises when I arrived. Was there a connection between the cases, and is glanders more prevalent than we realise, though undetected?

Case No. 3.—Subject. A black van mare, aged six, 15-3 hands high, the property of a wholesale grocer and provision merchant. Had worked sound until the previous evening, when she had returned to the stable rather lame.

Symptoms. The animal was resting the near fore foot with the heel slightly raised from the ground; when made to move, did so with difficulty and suffered great pain when weight came upon the affected limb. Examination of the foot revealed a "corn," but this was neither suppurating nor painful. One of the outside quarter nail holes was rather close, but no resistance was shown when the hoof was pinched. There was no ring or sidebone, and at that time no tenderness nor swelling of the coronet, but since, from the symptoms, I was convinced that it was a case of foot lameness. I ordered hot antiseptic fomentations and poultices, and awaited developments. In fourteen days there was no diminution of the pain, and a small area of the coronet was painful to the touch, this area being in size not more than a threepenny piece. On the seventeenth day I requested a second opinion, and next day I consulted a well-known practitioner, who agreed that the foot was the source of the trouble, and advised continuance of the hot applications for a time, expecting some visible change in the coronet.

The animal at this time was removed to my premises and placed in slings, as she had ceased to lie down and was rapidly losing condition. The off-fore leg was cedematous and sinking.

No change took place, and a blister was applied to the coronet, with the result that swelling of the coronet which had appeared was much enlarged. This was followed by iodine ointment; and eventually the swelling burst and discharged a thin yellow fluid. Healing took place rapidly, but the swelling had by this time extended all round the coronet.

Another blister was applied, and the animal sent to grass two months after the first sign of lameness, having to be conveyed to the field in a float.

Great improvement was noticed in a week or two, but the lameness returned, and for some time at intervals of about three weeks to a month, a soft swelling would appear. Each time the swelling was opened and a thin transparent yellow fluid was liberated, and the cavity syringed with antiseptic fluids, principally perchloride of mercury solution.

At the end of six months the animal could walk fairly well, but not soundly, and was sold and lost sight of. I consider this a case of suppurative coronitis, brought about by mechanical injury to the coronet, although at first I was much inclined to blame a binding nail.

Case No 4.—This was an aged black cart mare affected in the same way as the previous case, but in the off hind coronet. The lameness was caused in the first place by a tread in frosty weather, and this was neglected by the owner. On first impression quittor suggested itself, but the case proved one of coronitis,

and lasted for nearly six months, ending in sale before recovery.

In this case and the former, combined streptococcus and staphylococcus vaccine was used.

Case No. 5.—About a fortnight ago I was called to a light cart gelding which had been staked. He was a new purchase, and had been turned to grass about an hour when he seemed to stumble from the top of grain log and fall on a dry stake, which penetrated the abdomen a little to the left of the umbilicus. Examination of the stake showed it to have been buried to the extent of eight inches.

The wound was explored, and several small pieces of wood removed, after which it was syringed with a solution of lysol and a pad soaked in a solution of corrosive sublimate was applied and kept in place by means of a very broad bandage. On the first night, as the temperature was up and the breathing rapid, fomentations of hot water containing lysol were kept on all through the night. By morning urgent symptoms were relieved. Tetanin was injected as a preventive. The wound kept healthy and there was practically no discharge.

Tetanus developed on the ninth day, and in spite of further injections of "tetanin" the animal grew rapidly worse and died on the eleventh day.

Post-mortem showed the wound apparently healthy, but there was localised peritonitis and adhesion of the bowel to the abdominal wall.

Previously to this case I have had some remarkable recoveries from tetanus, using nothing but quiet and "tetanin" injections, and so had great faith in the latter as a preventive.

Case No. 6.—A case of a parturient cow which had prolapse of the vagina, accompanied by much straining. Examination showed that she was not prepared for delivery. A difference of opinion had arisen in regard to the application of sutures in such a case, and he desired to hear what the practice of country members was.

DISCUSSION

Mr. CARTER asked whether in Case No. 1 there was penetration to the joint. The reply was negative.

Mr. PRICE said in cases of prolapsed vagina he should certainly use sutures, even when the cow was near parturition. If the cow went worse and the pains came on the sutures could readily be taken out. He often used West's clams in these cases with good results.

Mr. LLOYD bore out Mr. Price in regard to suturing. When a vagina is exposed it is liable to injury from other animals, and he knew a case where an attendant had put a fork through it. In the case of tuberculosis he asked whether there was any particular stiffness of the spinal column, particularly about the neck and whether Mr. Burdred had considered testing with tuberculin. He instanced a case which was in a chronic state of waste; it was in a loose box about four weeks and if held by the nose had great difficulty in turning. The temperature was high, and it was impracticable to apply the tuberculin test. We diagnosed tubercle, and this was confirmed by post-mortem.

Mr. NOEL PILLERS referred to the case in which tetanin was injected as a preventive, and he presumed that anti-tetanic serum was meant. If so he failed to see why tetanus should supervene, as the serum was reliable. Was the serum from a good firm and was the dose sufficient?

Mr. EDWARDS was interested most in the case of ulcerated coronitis. One often saw such horses and there is no doubt about the lameness and subsequent enlargement accompanied with a dark-red jelly-like material. He had also seen the same on the inside of the fetlock joint. He wished to know whether in Mr. Burdred's opinion these cases were due to injury.

Mr. CARTER mentioned a case in a horse with foot lameness. He examined the foot carefully but could not discover anything, there was no swelling nor enlargement of the coronet; poultices were applied. In the course of a week there was enlargement all round the coronet. The ulcer burst and there was this jellified condition. The horse was subsequently destroyed, and on post-mortem examination he found it to be the navicular bone which was affected.

Mr. BRITTLEBANK congratulated Mr. Burndred for his practical paper. He wished to know whether in carrying out the post-mortem on the horse supposed to be suffering from tuberculosis, any other lesions were found, especially if a careful examination had been made of the lymphatic glands. The lesions appear to be somewhat unusual as compared with conditions commonly seen in cases of bone tuberculosis and on the evidence it is difficult to come to any definite conclusion. Probably the essayist's diagnosis was correct, but, to him, it appeared doubtful without further evidence.

In regard to cases of prolapsed vagina prior to parturition, this, in his experience, happens very commonly in aged and debilitated cows. One has also seen it very commonly in ewes. Personally his cases did much better by using sutures than by clams. It was curious how experience in practice could differ. Mr. Price liked in these cases to put on Wests' clams in his experience, and he had often used them; he had had very few satisfactory results, in fact to be candid he considered that the use of them was often attended with a good deal of unnecessary cruelty. He agreed with Mr. Burndred that it is an excellent plan to pack the hind quarters as high as it is comfortable to place them, but it is not always easy to get a suitable bed and retain the animal in position.

Mr. BURNDRED, replying to various questions, said he did not use tuberculin in Case No. 1, simply because he did not suspect tuberculosis. He did not examine the lymphatic glands. In Case No. 5 he did use anti-tetanic serum, which was obtained from the Pasteur Institute. In the case of coronitis the fluid was straw-coloured, but in Case No. 3 he got the red jelly-like fluid. He thought such cases were due to injury.

Mr. BRITTLEBANK moved a vote of thanks to Mr. Burndred, and in doing so wished to thank Mr. Burndred personally for the very kind and ready response to his invitation to bring a paper before the Society. It was no easy matter at times to induce people to step in and contribute for the welfare of the Society. In no less degree were the thanks of the Society due to those who had brought specimens. He had therefore particular pleasure in moving the vote of thanks to Mr. Burndred and those other gentlemen who had assisted.

Mr. CARTER, in seconding, said the specimens had been of a highly interesting nature.

The PRESIDENT, in supporting, remarked that the duties of the officers were considerably relieved when members came forward so readily to contribute to the meetings.

J. W. BRITTLEBANK, Hon. Sec.

THE CENTRAL VETERINARY SOCIETY.

The annual meeting was held at 10 Red Lion Square, London, W.C., on Thursday, 2nd Oct., Mr J. W. McIntosh, president, occupying the Chair.

The following Fellows signed the attendance book:—Messrs. G. Gordon, H. D. Jones, H. J. Parkin, Prof. G. H. Wooldridge, J. B. Buxton, Vet.-Capt. G. Rees-Mogg, W. Perryman, W. S. Mulvey, G. D. Martin, E. Lionel Stroud, R. J. Foreman, S. H. Slocock, W. R. Clarke, P. W. D. Smith, R. Bennett, G. H. Livesey, D. H. Wood, and Hugh A. MacCormack, hon. sec.

Visitor: Major Pallin.

On the motion of Mr. Mulvey, seconded by Capt. Rees-Mogg, the minutes of the last annual general meeting were taken as read and confirmed.

CORRESPONDENCE.

The HON. SEC. read a letter, dated July 25th, from Mr. Fred Bullock, Secretary of the R.C.V.S., acknowledging receipt of a letter enclosing resolution passed at the July meeting of the Society.

Also a letter from Prof. Woodruff, acknowledging letter informing him that the Society had conferred upon him its Honorary Fellowship. Prof. Woodruff thanked the Fellows sincerely for the honour thus conferred upon him, and stated that he would always remember the happy nights he spent with them at their meetings.

Letters regretting inability to attend the meeting were received from Messrs. J. C. Coleman, A. L. Butters, and J. Willett.

The HON. SEC. announced that the following Fellows had resigned: Messrs. Arthur Broad, T. C. Gillard, T. M. Hunt, and F. H. Sanderson.

On the motion of Mr. R. J. Foreman, seconded by Mr. W. S. Mulvey, the resignations were accepted with regret.

Nominations for Fellowship.—Vet.-Major W. A. PALLIN, Royal Horse Guards; and Mr. G. P. MALE, Reading, were nominated, and will come up for election at the next meeting.

ANNUAL REPORT AND BALANCE SHEET.

The HON. SEC. read the following annual report:—

Mr. President and gentlemen,—The Council has pleasure in announcing that the Session 1912–13 has been a very successful one. Thirteen Fellows have been elected, and four have resigned. We have to deplore the death of an old and active Fellow—Mr. A. Rogerson.

The annual meeting was held in October, at which Mr. J. W. McIntosh was unanimously elected President. Ten ordinary and two Council meetings have been held, with an average attendance of 36 at the ordinary meetings.

In November the annual dinner was held at the Holborn Restaurant, at which 94 were present.

At the December meeting the President gave the customary address.

We have to thank the following gentlemen for reading papers and introducing improved instruments during the Session:—Mr. G. H. Livesey, "Notes on some problems of everyday Dog Practice"; Mr. Henry Gray, "Tuberculosis in the Dog, Cat, and Bird"; Mr. F. W. Chamberlain, "Eczema in the Dog"; Prof. F. Hobday, "The Veterinary Profession and the Animal Anæsthetic Bill." Demonstration of a new electrical apparatus for the administration of chloroform vapour and description of a chloroform mask, suitable for the horse either when standing or cast, by Prof. F. Hobday. The several papers were thoroughly discussed, and a noticed feature was the large numbers who took part in the discussions.

Circular letter from South-Eastern Veterinary Association re fees paid by insurance companies. Circular letter with scale of fees and allowances payable to veterinary inspectors, from the N.V.A. Southern Branch. Mr. R. J. Foreman delivered his report of the Royal Sanitary Institute Congress at York. Mr. J. W. McIntosh was appointed to represent the Society at the Royal Sanitary Institute Congress at Exeter, and his report will be given in due course.

We beg to remind you that next year the Tenth International Veterinary Congress will be held in London, and those gentlemen who have not yet subscribed to the fund are urgently requested to do so.

Your Council are very pleased to note the numerous interesting and instructive specimens brought to the meetings, and they hope Fellows will continue to do so.

We beg to thank the following Fellows—Prof. Wooldridge and Reynolds, Messrs. Price, Jones, Macdonald, Foreman, Davis, Neish, Eaglesham, F. J. Taylor, Stewart, Bennett, S. L. Slocock, Hobday, and Buxton.

The balance brought forward and receipts for the year amount to £152 14s. 5d., the expenses £78 1s. 7d. and the sum of £10 10s. has been placed to capital account, leaving a balance of £64 2s. 10d., which the Council consider very satisfactory.

Prof. G. H. WOOLDRIDGE, in moving the adoption of the report, thought it was a very satisfactory one in every respect, both financial and otherwise.

Mr. R. BENNETT seconded the motion, which was carried unanimously.

On the motion of Mr. Mulvey, seconded by Mr. Perryman, the Hon. Treasurer and Hon. Secretary were appointed scrutineers of the ballot for the election of officers.

ELECTION OF OFFICERS.

The PRESIDENT (Mr. J. W. McIntosh) said they had now reached that stage of the proceedings when he was about to vacate the chair, but before he did so he desired to thank the Fellows of the Society for the support they had given him during the past year, and for the kindness and courtesy extended to him during his term of office. He wished especially to thank the office bearers, the members of Council, Auditors, and the Treasurer for looking after the finances of the Society in such an admirable way; and he particularly wished to thank their energetic Secretary for the earnest and thorough manner in which he carried out the work of the Society. It was necessary to occupy the chair only for a very short period to obtain a profound admiration for the intense enthusiasm which Mr. MacCormack threw into the conduct of the work. It was customary for the President to nominate his successor, and he had much pleasure in proposing that Prof. Wooldridge should be elected President for the ensuing year. (Cheers). No words of his were needed to commend the nomination. Prof. Wooldridge had been an active member of the Society for many years; he was a regular attendant at its meetings, and he was ever ready and willing to contribute from his store of knowledge in the form of papers or the discussion of them. He felt honoured to have the privilege of proposing him as his successor. (Cheers).

Mr. R. J. Foreman seconded the motion, which was carried by acclamation.

Mr. MCINTOSH, in vacating the chair in favour of his successor, congratulated Prof. Wooldridge on attaining to the position, and expressed the hope that his period of office would give him as much pleasure as his (Mr. McIntosh's) period had given to him.

The chair was then taken by Prof. Wooldridge amid hearty cheering. He briefly thanked the Fellows for the honour they had paid him.

Mr. SLOCOCK, in proposing a very hearty vote of thanks to Mr. McIntosh, the retiring President, said that in its time the Society had had some excellent Presidents, but it had probably never had one who had carried out the duties in a better and more impartial way than the retiring President. (Cheers).

The PRESIDENT (Prof. Wooldridge) said the sentiments Mr. Slocock had expressed were so obviously the feeling of the meeting in general that it was not at all necessary the motion should be seconded. He endorsed every word Mr. Slocock had said, and personally felt the difficulty in which he would be placed in following such an excellent President.

Mr. J. W. MCINTOSH thanked the Fellows most sincerely for their kind vote of thanks. If his efforts had satisfied them he felt more than rewarded. (Cheers).

Vice-Presidents—A ballot was then held for the election of four Vice-Presidents, and as a result the

following gentlemen were elected: Messrs. J. W. McIntosh (retiring President), F. Willett, W. S. Mulvey, and G. H. Livesey.

Council. Ballots were then taken for the election of twelve members of Council. The first ballot resulted in a tie between Messrs. Davis, Price, and Gosling for the last two places, and the second ballot resulted in Messrs. Price and Gosling being elected. The following is the complete list—Messrs. W. Hunting, Macqueen, Harrison, R. J. Foreman, W. Perryman, J. Willett, S. H. Slocock, W. A. D. Smith, S. Villar, J. B. Buxton, T. S. Price, and J. A. Gosling.

Hon. Treasurer.—On the motion of Mr. R. J. Foreman, seconded by Capt. Rees-Mogg, the retiring Hon. Treas., Mr. E. L. STROUD, was unanimously re-elected, the President stating that it was impossible for the Society to make a better choice.

Mr. STROUD thanked the Fellows very sincerely for their renewed vote of confidence, and stated that it gave him very much pleasure indeed to look after the funds of the Society.

Hon. Sec.—Mr. J. W. McIntosh, in proposing the re-election of Mr. H. A. MACCORMACK as Hon. Sec., said the Society could not do without him.

Mr. BUXTON seconded the motion which was carried by acclamation.

Mr. MACCORMACK briefly acknowledged the compliment, thanking the Fellows for the further honour they had conferred upon him.

Trustees.—On the motion of Mr. J. W. McIntosh, seconded by Mr. Perryman, the Trustees, Messrs. Woodger, Butters, and Slocock, were unanimously re-elected.

Auditors.—The retiring Auditors, Messrs. W. L. Harrison and W. Roger Clarke, on the motion of Mr. Slocock, seconded by Mr. Perryman, were unanimously re-elected.

Dinner Committee.—It was unanimously resolved, on the recommendation of the Secretary, that the Dinner Committee should consist of the senior officers of the Society: The President, Secretary and Treasurer, and Messrs. McIntosh, J. Willett, and Prof. Macqueen, the Committee being empowered to co-opt another member if they so desired.

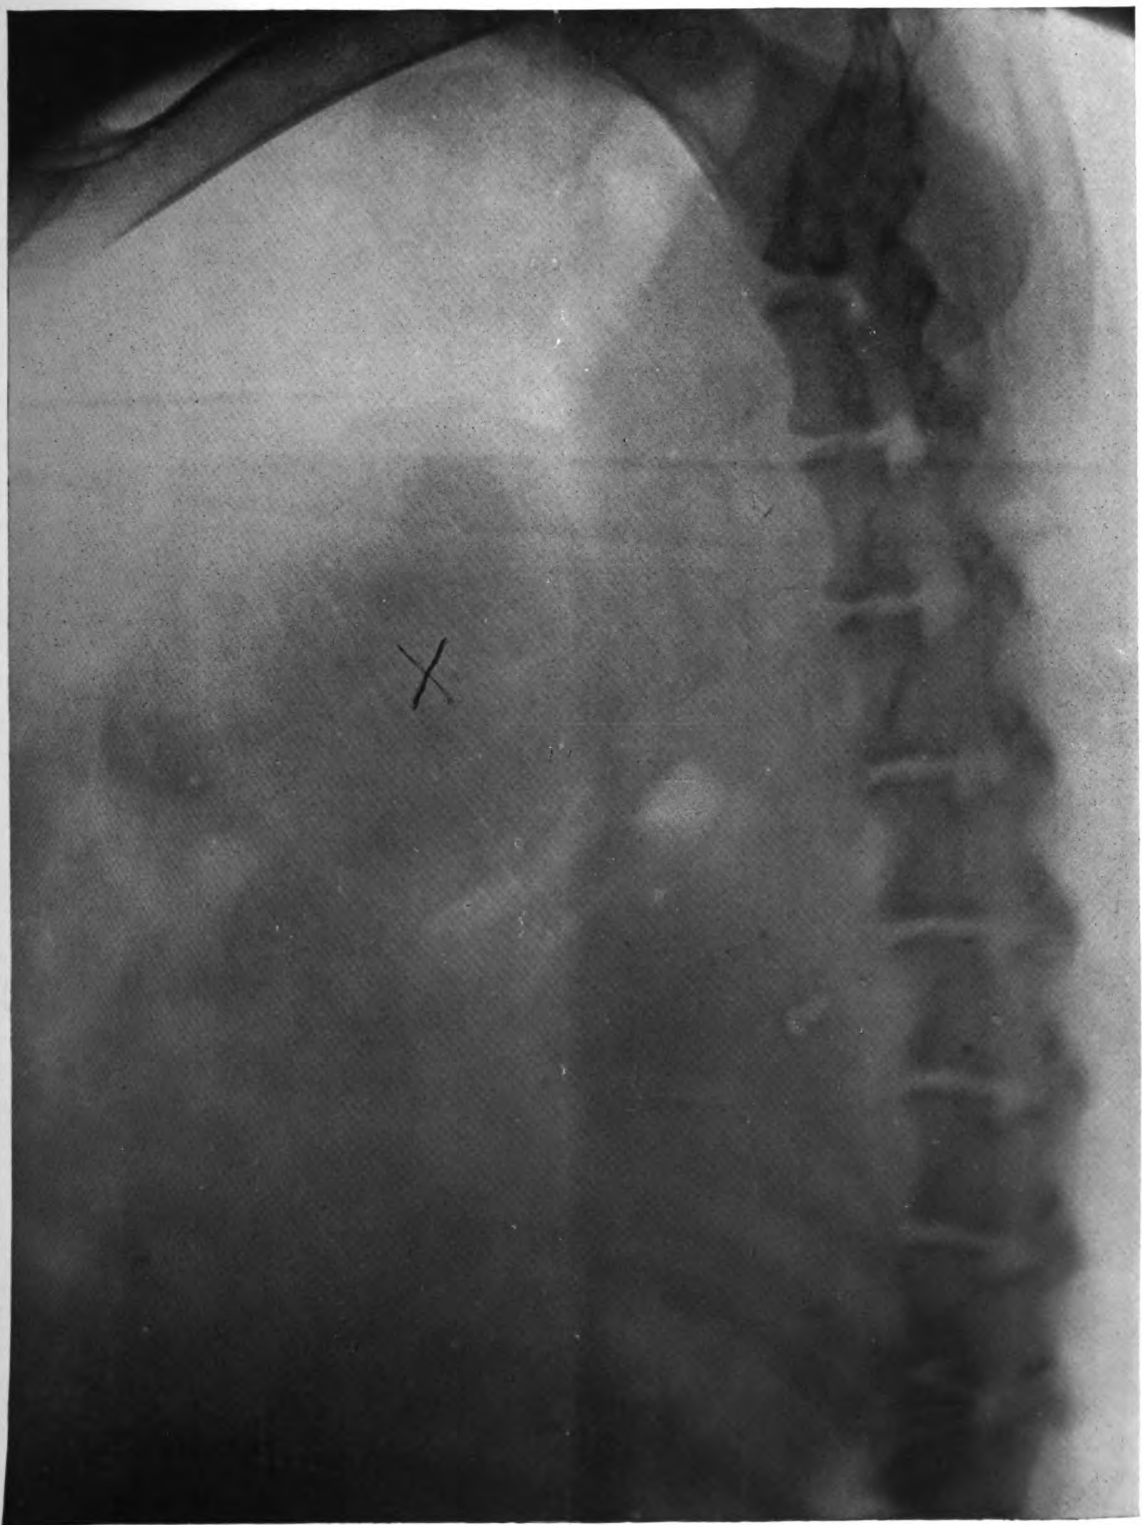

The PRESIDENT said he presumed it was the desire of the fellows that the practice of inviting ladies to the dinner should be continued. From his own point of view he thought it added considerably to the enjoyment of the evening. (Hear, hear.)

Mr. FOREMAN thought the decision rested entirely with the President, a view which was confirmed by the Secretary.

The PRESIDENT said he was not aware he possessed such a power, and he should certainly decide in favour of the attendance of the ladies. (Cheers).

MORBID SPECIMENS.

Mr. LIVESEY exhibited some specimens of a parasite which seemed to him to be a form of bot or the larvæ of a fly which he found in a Yorkshire terrier. He did not know whether it came from the rectum, the stomach or the bladder; he presumed it came from the stomach. The little dog came to him for the purposes of quarantine; it had been detained for some weeks, and to all appearances was in perfect health. In the previous week, when his man was going his rounds, he found on the floor by the side of where the dog was sleeping, a patch of moisture and two of the parasites. Two of the parasites that he exhibited that evening were found on the blanket on which the dog lay. The dog lay on a blanket in a basket, which stood on a wooden platform on a linoleum floor. The morning after the two parasites were found on the blanket in the basket, a patch of moisture was found on the board alongside the basket, which on being brought down into the sunlight

TUMOUR IN THE ABDOMEN OF A DOG. (X)

To illustrate note by Mr. E. H. Stent, (Lancs V.M.A.)

was found to be swarming with grubs in all stages, from the size of a pinhead to a quarter-of-an-inch. The skin of the dog was absolutely healthy, and so far as he could see the dog was healthy in every respect. Where the parasites came from he did not know, and he had never seen anything like them before. He had shown them to five or six people who knew something about parasites, but they had not been able to tell him the name. He had ascertained that the dog came from Natal. He had shown the parasites to two people who came from that Colony, but they knew of no insect in the country which gave a larvæ of that description. If any Fellow could give a name to it he would be very much obliged, because the owner was very anxious about the dog.

Mr. R. J. FOREMAN said that in the previous year he had a dog brought to him, the owner insisting that it was passing parasites or grubs in the motion. As far as his memory served him they were more of the maggot class. Professor Woodruff kindly examined some of them at Camden Town, and on referring to some back numbers of *The Lancet* found that in the human subject, in children especially, such live parasites occurred. The children passed them at night. It was intended to see what the grubs matured into, but they all died.

Mr. LIVESY stated that so far the parasites had only been passed in the night.

The PRESIDENT (Prof. Wooldridge) thought there was no doubt whatever that the parasites were larvæ of an insect, and the circumstances under which they had been found lent considerable colour to the statement that they might either have been vomited or passed by the dog. But as none of them had been seen to be passed, and the fact that they varied in size from a pin head to a quarter-of-an-inch, made him think it was quite possible they were larvæ of insects that had been deposited on the moist patches of the kennel. To his mind it was not at all proved that they had ever been inside the dog, and although he was not able to identify them at once, he believed them to be of external origin. Mr. Livesey had kindly promised to give him the specimens, which he would submit to some authorities on the subject, and he would inform the members at a future meeting whether their identity had been established.

[Professor WOOLDRIDGE has since reported to the Hon. Secretary that he submitted Mr. Livesey's specimens to Dr. R. T. Leiper, who in turn submitted them to Dr. Alcock. The latter has identified them as larvæ of the lesser house fly (so-called), viz., *Homalomyia* (*Fannia*) *cunicularis*. That being so, it is unlikely that they were passed by the dog.]

The PRESIDENT exhibited, on behalf of Mr. Martin, a specimen taken from a cat. On examination during life, what appeared to be a pedunculated abdominal tumour was found, and the cat was anaesthetised with a view to its removal. On performing laparotomy and bringing the enlargement into view, it was found to be some new growth through which a portion of the bowel was passing, and closely associated with the omentum. Finding that the condition was quite inoperable, the cat was despatched, and on making a post-mortem examination the condition shown in the specimen was disclosed. Mr. Martin was not sure as to its nature, as he had not been able to make a microscopical examination, but he suggested the possibility of it being tuberculous. Personally, he (Prof. Wooldridge) had seen a number of cases of mesenteric tuberculosis of the cat exactly conforming to the specimen, and he had very little doubt that it was a case of mesenteric tuberculosis of the cat. He intended to have smears made for the purpose of obtaining a definite decision on the point.

[Since the meeting, Prof. Wooldridge has examined smears from the specimen and demonstrated tubercle bacilli in profusion.]

HUGH A. MACCORMACK Hon. Sec.

VETERINARY MEDICAL ASSOCIATION OF IRELAND.

The quarterly meeting was held in the Gresham Hotel on Tuesday evening, 26th August, the President, Mr. P. J. Howard, presiding. Also present, Messrs. McKenny, Watson, Reavy, Winter, Mahony, Holland, Thompson, Dunlop, Vahey, Dobbyn, Baker, Mason, T. F. O'Brien, J. J. O'Brien, Renchan, MacCann, Cushmanah, Heney, Hare, Healy, E. Wilson, and Col. Moore.

Mr. WATSON: I propose that the minutes of the last meeting be taken as read.

Prof. O'CONNOR seconded the motion.

There being no objections, the minutes were signed by the Chairman.

APOLOGIES.

Prof. O'CONNOR announced that apologies had been received from Messrs. Wilkinson, Hamilton, Patrick, and Profs. Mettam and Craig.

Mr. McKENNY: Mr. Allen asked me to apologise for him. He is sorry he is unable to be present.

The CHAIRMAN: Mr. Prentice sent a message also. Unfortunately he is unable to be present.

The SECRETARY read a report of meeting which he had received from the Munster Veterinary Inspectors' Association:

MUNSTER VETERINARY INSPECTORS' ASSOCIATION.

A meeting of the Veterinary Inspectors of Munster was held at Moran's Hotel, Mallow, on Monday, 23rd June, 1913. In the Chair: Mr. M. F. Lynch, M.R.C.V.S., Dungarvan. Also present: Messrs. J. Preston (F), Mallow; J. A. Hewson, Killarney; P. J. Walsh, Croom; D. Barry, Skibbereen; J. F. Mahony, Cork; T. M. Ryan, Limerick; M. J. Mitchell, Kilmallock; R. J. Murnane, Newcastle West; W. J. Foley, Tralee; A. Dobbyn, Waterford; W. Dagg, Dingle; C. P. Hynes, Lismore; M. F. Lynch, Dungarvan; J. J. Walsh, Youghal; D. M. Barry, Mallow; P. W. Creagh, Fermoy; W. Phipps, Bandon; W. Power, Tipperary; T. I. Alexander, Kinsale.

Proposed by Mr. C. P. Hynes, seconded by Mr. J. Preston, and passed unanimously:—"That an Association be formed to be called the Munster Veterinary Inspectors' Association, with the object of protecting the interests of the profession in connection with the administration of the Contagious Diseases of Animals' Act, more especially in connection with the Administration of the Tuberculosis (Ireland) Order of 1913.

OFFICERS.

President.—Mr. D. M. Barry. Proposed by Mr. M. F. Lynch, seconded by Mr. W. Dagg.

Hon. Secretary.—Mr. T. I. Alexander. Proposed by Mr. E. A. Phipps, seconded by Mr. J. A. Hewson.

Hon. Treasurer.—Mr. P. W. Creagh. Proposed by Mr. J. A. Hewson, seconded by Mr. R. J. Murnane.

Proposed by Mr. W. Power, seconded by Mr. D. M. Barry, and passed unanimously:—"That the annual subscription to the Association be 10s. 6d."

It was agreed that all present become members, and that the remaining veterinary inspectors of Munster be invited by the Hon. Sec. to join the Association. Further, "That four form a quorum at any meeting of the Association."

The following scale of fees in connection with the administration of the Tuberculosis (Ireland) Order of 1913, was adopted:

For clinical examination of each animal reported as suffering from tuberculosis	£1 1 0
Examination of each additional animal on same premises	2 6

Applying "tuberculin" test to each animal	1	11	6
Post-mortem	1	1	0
Microscopical examination of milk for tubercle bacilli		10	6

The above fees include mileage, any reports necessary, valuation, etc.

T. I. ALEXANDER, Hon. Sec., M.R.C.V.S.

Kinsale, Co. Cork.

Mr. WINTER : I have great pleasure in proposing that that circular be marked "read" without further discussion.

Mr. REAVY : I have great pleasure in seconding that.

The circular was marked "read," Mr. Winter's motion being unanimously agreed to.

MINUTES OF COUNCIL MEETING.

A meeting of the Council was held in the Veterinary College on August 15th, at 4 p.m. There were present Mr. P. D. Reavy in the Chair, Messrs. Dunlop, Heney, McKenny, Watson, Magee.

The minutes of the previous Council meeting were read, confirmed, and signed.

Apologies for non-attendance were received from Messrs. Mahony, Holland, Patrick, Wilkinson, Howard, Chambers, and Profs. Mettam and Craig.

A communication was received from the Munster Veterinary Inspectors' Association, and it was ordered that this be read and considered at the next general meeting.

It was arranged that the general meeting should take place at the Gresham Hotel on Tuesday, 26th August, being the first day of the Horse Show, at 7.30 p.m., and that Mr. Howard, President, be asked to read a paper.

The following accounts were passed for payment :—

H. & W. Brown, reprints	£1	2	6
Brindley & Son, printing	4	7	4
Clerical assistants' half-yearly stipend	5	0	0
	£10	9	10

The minutes of the last Council meeting were read by the Secretary.

The CHAIRMAN : These minutes have to be considered again at the next Council meeting. The Secretary has some accounts to be passed for payment, including £2 2s. for the reporter, and 15s. for the hire of a room in the Gresham Hotel.

New Members.—Mr. PATRICK DOLAN, Belgrave, Seafield Road, Clontarf, was proposed by Mr. Watson, seconded by Mr. McKenny.

Mr. T. F. O'BRIEN, M.R.C.V.S., Falcarragh, was proposed by Prof. Mason, seconded by Mr. McKenny.

BENEVOLENT FUND.

Mr. WATSON : At the last meeting of the Council I was asked to say a few words on behalf of the Victoria Veterinary Benevolent Fund. I resisted the temptation to speak on this subject for the reason that I feel that I am rather acting the part of the hypocrite, inasmuch as it was only this year that it was borne in upon me that I ought to become a subscriber. At any rate, I have got all the zeal of a convert. I think, as an Irishman, there are three characteristics which distinguish Irishmen, they are their lively wit, their love of sport, and their disposition to be benevolent. I have no great belief in the truth of this ; in fact, I would submit with great respect that the Irishman of to-day does not merit these virtues. I think we are living on a reputation earned in the past. I don't think we are as ready witted as were our fathers, I don't think we are as good sports, and I don't think we are as charitable. When a great disaster occurs, and a subscription list is opened for the relief of the victims, if you take the list of subscribers

you will see the number of Irish subscribers on these lists are few and far between. However, that is only a pious opinion of my own, and we have still a few who are imbued with the best traditional Irish characteristics in a prominent degree. In speaking of the work of the Victoria Veterinary Benevolent Association, I think few are aware that it is dealing out something like £52 to people in Ireland, and that at a time when it was not getting half that sum in subscriptions from this country. I appeal to members to be open-handed in supporting this Benevolent Fund. It is not creditable to Ireland that we, at least, do not defray our own debts, and I appeal to every member here to become a subscriber to this Fund, which is a most admirable one, and one that must appeal to all of us.

Prof. O'CONNOR : I am Secretary of the Committee which has been appointed to consider deserving cases in Ireland, and I endorse every word that Mr. Watson has said with regard to this Fund. It is needless to say how deserving it is. Some very pitiable cases come before me ; people in great distress, and with no means of living. It is a charity that members of our profession should support. As Mr. Watson has said, £52 is paid in Ireland to deserving cases, and there are others which require help. The amount subscribed by members of this Association is still small, every member should subscribe something—10s. 6d. makes one a member.

Mr. McKENNY : I am a subscriber to the Fund, and I don't think it right that Irishmen should be belittled as Mr. Watson has just done.

Mr. WATSON : Oh, no, I did not belittle them.

Mr. McKENNY : I say that Irishmen are not degenerating : on the contrary I think we are the same ready wits, the same manly spirited people and the same sportsmen as ever we were. What I do say is that as regards this fund the previous speakers have every reason to judge from the way we treat it that we are not as generous as heretofore, and therefore the charge that we are becoming less charitable would have to be endorsed. I therefore appeal to everyone of you to show that the Irishman is still animated by the same charitable spirit that characterised him in the past. (Applause).

Mr. FRED. HENEY, in response to the Chairman's report, said in urging the claims of the Fund, he was sure that Mr. Watson who had been deputed at the Council meeting to speak on behalf of the Victoria Veterinary Benevolent Fund had lucidly expounded the objects of the Fund and its claims to a liberal measure of support from the members of the Irish veterinary profession. The Veterinary Benevolent Fund had always appealed to him (Mr. Heney) and as long as he was privileged to be connected with that Association and its Council he would urge the claims which this Fund in England had upon the Irish branch of the profession. The case mentioned by Mr. Reavy was a strong example of what Mr. Shipley's Association has done, and is doing for our poor and necessitous brethren. I know of others who have been ably assisted, and I sincerely trust that by the few desultory remarks I have made some members present, not already subscribers, will examine their consciences and see if they cannot give at least 10/6 annually to this most deserving Fund.

The CHAIRMAN : I have appealed to the members on many occasions to help this Fund, and I don't think it needs any further remarks from me to commend it to you. It should be supported generously.

V.M.A.I. MEDAL.

Prof. O'CONNOR : I have to announce that Mr. J. P. Machattie obtained first place in the final examination for the diploma of the Royal Veterinary College, and is therefore entitled to the Veterinary Medical Association of Ireland's medal.

The CHAIRMAN: Is it the wish of this Association that we make an order to present Mr. Machattie with the medal usually given by this Association to the gentleman who obtains highest marks at the examinations?

Mr. REAVY: I beg to propose that the medal be given.

Mr. MAHONY: I second that.

The proposition was carried unanimously.

THE ADMINISTRATION OF CHLOROFORM TO HORSES STANDING.

By P. J. HOWARD, M.R.C.V.S., Ennis.

Long over a year ago our esteemed Secretary asked me to prepare a short paper on the administration of chloroform to horses standing. He says I promised to do so; that is my excuse for attempting to trespass on your patience with this subject.

In this age of motors and flying machines when, according to some people, the horse is fast becoming extinct, it may seem a waste of time and energy to discuss such a subject, but when one considers that a yearling colt can still fetch 5000 guineas in the public market and that 45,000 guineas is paid for a sire, and in fact that a horse is worth as much money as he ever was, and that many such valuable animals come within our domain for various operations, the importance of his care and control during such operations, is well worthy of our serious consideration. Moreover, as a scientific profession we are expected to keep pace with the march of science, and to be ever ready and anxious to take advantage of the most up-to-date scientific methods in the practice of our profession.

Further, the veterinary surgeon is more or less expected to be a lover of horses, and as such to be anxious to adopt the most humane methods as against the crude and barbarous ones often employed. I am not here to discuss any particular operation or form of operation, my remarks apply to all operations requiring the animal to be in the recumbent position.

In the performance of operations on horses one has to take precautions to have the animal under such control as will prevent the possibility of risk to the operator and his attendants, and also lessen the risk of injury to the animal itself; it is only thus that one renders possible operations that could not otherwise be attempted.

It will scarcely be disputed that most, if not all, surgical operations will be much more happily performed if the animal is under the influence of an anæsthetic. There are several useful preparations that induce local anæsthesia, but for all important operations one wants the animal in complete anæsthesia, and the only general anæsthetic for horses, so far, is chloroform.

Now, as I have already said, it will scarcely be disputed that all important operations on the horse in the recumbent position are easier for the operator and ever so much happier for the horse and the person who owns him if he is under the influence of chloroform; and yet the use of chloroform is by no means general in the veterinary profession. Why this should be so, it is difficult to explain, and still more difficult to understand. Of course you are all aware that a Bill is being promoted in Parliament to make compulsory the use of chloroform in certain important operations on the horse, and judging from the columns of our veterinary press, the introduction of this Bill created a scare, and almost a panic in the ranks of the veterinary profession. Members have written to condemn the use of chloroform, who have never mastered the use of it; and who possibly through fear compel themselves to be blind to its advantages.

I rather think that the present restricted use of

chloroform is due to a misconceived and highly exaggerated notion of the dangers supposed to be inseparable from its use. Doubtless those ideas of great danger arose from the experience of the very painful and sometimes prolonged and dangerous struggles that are observed when horses are undergoing the effects of chloroform after they have been already cast and hobbled. By administering chloroform while the horse is standing, there are none of those painful struggles, and the dangers, if any, are reduced to a minimum.

It has been my practice now for many years to give chloroform standing to horses of all ages, and for all operations, and I have never seen any ill results, though I have operated on hundreds of horses and often with very little help and under very adverse circumstances.

I have heard from practitioners of some cases of collapse and death, but the horse that won't stand a dose of chloroform can scarcely be considered a loss, and must be such a very bad case of heart disease that he is better dead.

In general practice one has to deal with untrained or unhandled horses as well as with trained ones, and it is with the wild young ones that this method of administration is particularly useful.

Now I know that some of our great men will, and do, ridicule the very idea of asking a veterinary surgeon to deal with an unhandled horse. They think it is almost *infra dig.*, and they will say a veterinary surgeon must not be a horse trainer or a horse tamer; but without requiring him to be either, I fear that he cuts a rather sorry figure at times if he cannot show that he knows how to handle a horse, or at least direct how it should be done; and it will not take from his dignity either as a man or as a practitioner if he is capable of doing it himself.

Trained or untrained, the horse will always be best in an enclosure, and when convenient in a good sized loose box. He should, of course, when possible be fasted overnight.

With the untrained wild young one the quickest and best way to catch him is with the lasso. Throw your rope on his neck and twist the two ends till it tightens on the neck, or pull one end through a noose at the other end and squeeze. It will take a few good men at times to hold on to the rope; and it is only when almost suffocated that some wild young horses will allow you to lay a hand on their heads.

I find that a good firm grip of an ear will quiet most young ones; but the ear must be held once it is gripped.

You can now put on the cavasson or halter, and if the horse is a very wild one, it is perhaps easier to put on the chloroform muzzle at the same time. I have an adjustable cavasson that fits big and small, and I find it very useful.

My chloroform muzzle is simply a leather bag with a strap to go over the head and with a slit at the side to permit a large sponge. The old one that has done duty for many years is here for inspection and, as you can see, it is not an elaborate affair, and there is nothing that can hurt. The muzzle fits into the mouth and covers the nostrils well. I prefer the muzzle in the mouth as I think it may prevent the tongue being injured by the teeth squeezing on it when the animal is under the influence of chloroform.

But any kind of muzzle will do; in fact anything that will exclude the air and hold a sponge or wad of wool on which to pour the chloroform. I have more than once used a small sack, or made a muzzle by folding a cotton flour sack or towel and tied it on to the head collar.

You may elect to operate in the loose box or outside, as you please, the procedure is the same, and for all horses. There is no doubt that when the box is suitable the horse is quieter and goes under more readily.

If you are to have the horse outside see that your cavasson and lead are sound, and instruct your man not to let the horse get away if he happens to make a plunge.

Having adjusted the muzzle you simply pour the chloroform on your sponge or wad of wool, and place it in the muzzle. For yearlings I always pour on about 2 oz.; for an extra strong or wild one and for a two-year-old $2\frac{1}{2}$ to 3 oz.; and for three-year-olds and for trained horses always begin with 3 oz.

There is little need to measure exactly the amount, you can easily accustom yourself to make a fair guess by noting the amount in the bottle with your fingers. After about three minutes the animal begins to show signs of becoming dazed, the eyes stare, and you will soon notice that he cannot see.

With animals in a loose-box, they seldom move at all, but horses outside may step backwards a few yards, or occasionally try to walk on. Seldom will one plunge, and I don't remember that I have seen one rear, which is the great danger alleged by those who have not tried. Sometimes, just as a horse gets the first sniff, and perhaps before you have secured the sponge, he may plunge, and you may have to get his ear held till you have secured the sponge in the muzzle.

Once the sponge or wad saturated with chloroform is secured in the muzzle, the trouble is over. If the horse is restless, let him walk round in a circle, but don't let him get away; it is at least as easy to hold him now as it would be without the chloroform.

When you notice that the horse is going under, you may now strap up a fore leg; that will generally induce him to kneel down, and in another minute he will lie down, or you may push him over.

I have seen horses lie down in four minutes, and I have seen some not go down for eight or ten minutes, but in no case have I ever seen any struggling after they had gone down, and a horse will lie quietly for seven to fifteen minutes without further restraint. Of course, when the operation is a prolonged one you must administer further chloroform as required.

You may strap up the fore leg before giving the chloroform, but I prefer to do so after I see the horse is getting dazed.

Now as it is necessary in most cases to fix a limb or limbs, so as to keep the animal in a particular position, and as such fixation has to be done with hobbles, I find it is much easier and more useful to put the hobbles on the horse before he goes down. In fact, my practice now is to put him down and not to wait till he lies down; and, further, you can put him down exactly where you want to. I always use the ordinary colt rope, or side lines, and for all horses.

Some horses may, when left to lie down, remain long on their knees before going over, and may even require a larger dose of chloroform, but I find that with the doses I have described, the horse is dazed in three to five minutes, and by putting on your ropes, you can induce him to lie down without trouble, and that once he is down there is no further struggle, and he is fit for surgical operation immediately.

You, of course, leave the muzzle on during operation, and remove it at once when the operation is finished. Remove your hobbles quietly, and let the horse lie as long as he cares to.

When the operation has not lasted more than ten minutes, the horse is generally ready to get up in a few minutes, and when he is on his legs for two or three minutes he is perfectly recovered from the effects of chloroform.

Those after effects that one hears so much about must, I think, exist only in the imaginations of those who have described them. I have never seen any such, and I have had horses down for 40 minutes, and used five to six ounces of chloroform. When the operation

has been a long one, it is best to induce the horse to lie as long as possible. With ordinary care there is little danger from overdose or after effects.

In 1897, at the request of his lady owner, I destroyed with chloroform the celebrated thoroughbred sire "Turco," and he inhaled 11 ounces of chloroform before he was dead.

I have seen a yearling colt gallop and jump a four-foot wall two or three minutes after he stood up from the operation of castration, though he was sufficiently under to be operated on without a hobble.

I have on a previous occasion given the record of a number of cases of colts, one and two years old, for the operation of castration. The average amount of chloroform used was $2\frac{1}{2}$ ounces, and the average time taken with the operation was seven minutes. All those colts were allowed to go under without pulling down with hobbles, and were operated on with the upper hind leg just pulled out of the way with a web lead.

I have castrated stallions up to *fourteen years old*, and have performed various other operations on old horses, and have given all chloroform standing. Under ordinary circumstances, and with ordinary care, by this method you can, with two boys, easily manage an operation that you could not otherwise attempt without six good men.

I do not claim to belong to the brigade of lightning operators, or acrobatic surgeons, but I have castrated a two-year-old thoroughbred colt in his loose-box, given chloroform standing, and did not use hobbles, and was only *eight minutes* on the premises.

I fear I would only bore you with statistics; I have tried to give you a description of the method that has been, with me, a great success. I fear I have not been able to give you a very brilliant, or a very graphic description, but I hope I have given sufficient to dispel from your minds that there is any mystery about giving chloroform to horses standing, and I hope that what I have said may induce you to give this method a fair trial, and I am certain you will be convinced of its advantages.

Who has ever watched a horse being thrown with the ordinary chain and hobbles without feeling that he got a great, unmerciful, unnecessary heave, which made one feel and wish there could be a happier method. And who has watched the struggles of a horse when undergoing the effects of chloroform after he has been hobbled and thrown, and not thought that the horse is suffering more by the process than he may from the surgical operation that he is about to undergo.

Chloroform standing is, I believe, the ideal method; and I am strengthened in that belief by the good accounts that I hear from those whom I have induced to try it. Don't be disappointed with a failure or two, persevere, and get confidence in yourself, and once you get expert in the administration of chloroform you will do away with a lot of hard labour in your work, and you will by its more general use advance the practice of our profession on a scientific basis, and as I have repeatedly said, you will in that way do more to exterminate quackery than could ever be done by Act of Parliament.

Mr. WATSON: In order to relieve Mr. Howard of the dual position of Chairman and Essayist, I beg to move that he do now leave the Chair, and that it be taken by Mr. Holland.

Mr. WINTER seconded the proposal, which was passed.

Mr. HOLLAND having taken the Chair,

DISCUSSION.

Mr. McKENNY: I have very great pleasure, before entering on the discussion, in thanking Mr. Howard for his very able paper, but I would say that it is more than able. It is most unusual, inasmuch as he has come before this Association of scientific men to upset

all theories and all practice that we have known previously, but there may be a large number of practitioners who feel, after hearing that paper read, that our theories and science relative to this subject may be put aside. That, in effect, is what Mr. Howard has told us, and it is a very courageous thing to do. In using chloroform we have always been told that there is a stage of excitement, but, according to Mr. Howard, that stage does not exist in practice. He has also made a new departure in the amount of chloroform to be given. He has upset all theories. But my experience in the use of chloroform does not coincide with Mr. Howard's. I found so much excitement that I am afraid to give chloroform to horses standing. As for instance, I was asked to castrate a stallion—a very wicked brute he was. He kicked a man and broke his arm, and he nearly trampled another man to death. The owner would not allow me to operate without giving chloroform. I had a muzzle something similar to the Carlisle bag. I thought I would make sure that I would give him enough. I gave him four ounces to begin with. The horse, immediately he got the smell of the chloroform, became almost mad. Everybody left the box, but the last man forgot to shut the door, and the horse got out into the paddock. I never saw a horse really mad until I saw that one. He dashed at an iron fence, came back, and dashed at it again, everyone cleared out of the paddock. I got behind a tree. Fortunately I had put a cavesson and rope on the horse, and as he passed the tree I caught hold of the rope and managed to get him down, and got him secured. That horse got four ounces of chloroform, and he did not simply and quietly lie down, as Mr. Howard, who has a much larger experience of this matter than I have, tells us. I have ceased now to give horses chloroform standing. Prof. O'Connor chloroformed three horses in my yard, and it was not our experience that there was no stage of excitement or that the horses did not suffer any after effects. They did not get up quickly, and walk away. One of the horses, one of my own I may add, was three-quarters of an hour after the withdrawal of the chloroform before he became conscious and able to stand. It is my experience that the administration of chloroform to horses while standing is highly dangerous, and that there is a stage of excitement in which they become most unruly, that there is a semi-conscious stage in which they stagger about until ultimately they become unconscious and fall heavily in a helpless condition.

As regards lassoing, I have a great objection to it, as I can never find any one in this country who is able to do it successfully at the first attempt. I have a plan which I find works well, and that is by taking the rope over the backs of other colts, slipping it over the neck of the one you want to secure, and then twisting up the rope until it is tight on the neck. The practice of calling "whoa, whoa," is bad, and I always enjoin silence. I am delighted that Mr. Howard has come forward and has given us his experience. I have no reason to think that he is telling us deliberate falsehoods; there must be something in his method, and I hope that it may be possible for him to give us a demonstration, and perhaps it could be arranged for this week.

As these discussions are intended to elicit our various experience and opinions, with the view of advancing knowledge, with the Chairman's kind permission, I will ask you to consider specially that, although some of the speakers have advocated chloroforming horses standing, yet some of them recommend that when the horse is semi-conscious from the effects of the chloroform it should be hobbled and cast. I ask, why run the danger if the horse is going to lie down quietly? Again, other speakers have told us how they saw horses chloroformed standing. One gentleman described how it was accomplished in a padded room, with a rope on

each side of a cavesson fastened on to the horse's head, and the ends of the rope passed through pulleys on the side of the walls and extending outside the room, so that it could be manipulated as required outside the room, as no one remained inside. Again I ask, if there is no danger in chloroforming horses standing, why take these precautions and go to so much expense?

Another gentleman states that previous to administering the chloroform, the horse should be taken into a large field with a cavesson on his head, and a rope attached to each side of it, so that the animal can be controlled and allowed to fall as desired, in other words, to keep its head straight, fearing that in falling it might break its neck.

Mr. WINTER: I desire to thank Mr. Howard for his innovation. I have administered chloroform to horses on several occasions standing. I have given it in a field and in loose-boxes, and I intend to try Mr. Howard's method some day soon. There are one or two things with which I do not agree. The amount of chloroform is excessive. I use Duncan and Flockhart's. I tried Wellcome's, but I prefer Duncan and Flockhart's. I find two to two and a half ounces quite enough, and I never give more than four ounces for any operation. About operating on colts without sidelines, I would like to know how Mr. Howard would operate, say in the case of a horse where the hock had to be fired. Then another point, I don't think you will get complete anaesthesia without securing the horse. I generally like to have the horse well secured, because you will have a struggle, it is inevitable in cases where you have to perform operations in which you touch large nerves. The animal feels it, and there is always a struggle. I don't think then it is fair to one's insurance company to operate on horses without having them properly secured. For castrating colts, I invariably put on the knee strap first, and slip on the other tackle later. Chloroforming horses out of this world, I think is as slow and terrible a method as ever I heard. A far quicker way is to use the humane killer, and I never saw a horse fired at a second time. It is certainly the quickest way of dispatching an animal. I have had only one death in chloroforming horses, and I have had an unhappy experience in chloroforming dogs. The horse was a three-year-old "rig," bought for some £25, and I was asked to operate. I put the muzzle on the horse, and he was brought out, and the peculiar thing was that in the next three minutes he was dead. A post-mortem revealed the fact that he had one of the most enlarged fatty hearts that ever I saw. Mr. Howard's method is a revolution in chloroforming horses, but I should not like to tackle major operations on horses without having them well secured. It is wonderful how much a horse can struggle, even when under chloroform. I thank Mr. Howard for his innovation, but I should not like to try giving chloroform to horses standing with the assistance of the class of men that one has to put up with on some occasions, or with the owner about, for he would probably get you into such a stage of excitement that the operation would not stand much chance of being successful. My experience is, that the time to get a horse under is from seven to ten minutes for minor operations, and for other operations for which one wants complete anaesthesia, fifteen minutes, but for ordinary operations from seven to ten minutes is enough. A good deal depends upon the chloroform you use. You will not get as good results with a bottle that has been opened and used on a previous occasion, as with a new bottle. You want to buy chloroform in small quantities, and Messrs. Duncan and Flockhart have small stoppered bottles which are admirably suited for the purpose.

Mr. RENEHAN said he had never administered chloroform to horses standing. He had used chloroform for twelve or thirteen years and had never had any trouble.

Col. MOORE (Assistant Director Army Veterinary Services): I wish to thank Mr. Howard for his paper and to support him. To do so I should like to go back 30 years, and bring to notice the man who was the real father of the administration of chloroform in Britain, the late Mr. Roberts, of Tunbridge Wells. Thirty years ago he was a practitioner in Kendal, Westmoreland, and I was his pupil. It was his rule to give chloroform for all operations, and he gave it standing. He did a good many castrations, and it is in connection with these castrations that I should like to say a few words. His rule was to use an ordinary leather nosebag covering the nostrils. This he usually put on in the stable, then led the colts into a field where he manœuvred them. He attached a cart rope at its middle to the ring of the head collar, giving each half of the rope to one or two men with instructions to keep always at right angles to the colt. Chloroform was then introduced into the bag by means of a sponge and as the colt began to sway under its influence the men pulled the rope at either side and the animal went down on the right or left side as desired. At first he found that the animals were not going under the influence of the chloroform quickly enough, but by means of a towel round the top of the muzzle he excluded the admission of so much air, and found they went down much quicker, in fact by this process they were got under the influence of the chloroform in three minutes, and the operation was generally over and the colts on their legs again in about fifteen minutes. Mr. Roberts read a paper at a Veterinary Medical Association at Carlisle on his method of administering chloroform, and shortly after the Carlisle chloroform inhaler was produced and put on the market.

As we all know, Mr. Roberts was a practical man, and I particularly wished to come here to-night and to speak of his methods in his memory. He died, I regret to say, a few weeks ago, and I want to pay this tribute to his memory. I always look upon him as the father of the administration of chloroform to horses standing. He never used any other chloroform but Duncan and Flockharts.

Mr. McKENNY: Was there no stage of excitement?

Col. MOORE: There is generally supposed to be a stage of excitement at the beginning, but if you give the chloroform strong enough, *i.e.*, without the admixture of too much air, you certainly do not get very much of it. Personally I don't think one meets with an excitement stage. It is, at all events, a negligible matter. I have had chloroform myself four times, and I remember on the last occasion, about two years ago, I determined to take notes of its effect on me. However, there was no time for notes. After the second deep breath I was off into oblivion in a moment, and all I can remember was that the line between sensibility and insensibility was most abrupt.

Mr. McKENNY: Do you consider it would be dangerous to cast horses in any other way except the way Mr. Roberts did?

Col. MOORE: I don't think so.

Mr. McKENNY: Why did he do it?

Col. MOORE: It was his custom to do it, and there was less danger in the field than in the loose box.

Mr. McKENNY: Was there no danger?

Col. MOORE: I don't think there was any danger. Chloroform usually affects the hind quarters first, and it is quite common to see animals for a few moments sitting on their haunches and swaying on their fore legs, still on the ground, before finally going down prone.

Mr. THOMPSON: I have only had a limited experience of the use of chloroform given in the standing position, but it goes to show that the danger, if any, is very small indeed. Horses go under the influence quickly without any apparent stage of excitement, and the amount required largely depends on the age and temperament of the animal. The last animal on which I

operated was a thoroughbred five-year-old stallion, and it took the unusual quantity of 5 oz. to put him under. For young colts about 2 oz. is sufficient. In firing horses under chloroform I don't find it necessary to secure them very much. A few months ago I fired the hind fetlocks of a horse without putting a single rope on him; and during the whole operation the horse never winced once.

As to lassoing horses, Mr. Howard has described his method, which is the one usually adopted in this country. But I remember having seen a very ingenious way of catching young horses in England: that was a staff about twice the length of the ordinary walking stick, with a crook at one end on which a halter with a long shank was fixed, and slipped over the colt's head.

Mr. O'BRIEN (Falcarragh) said he had been with Mr. Howard, and it was remarkable how easily he put horses over. There was absolutely no trouble, and no excitement. There is one case of which Mr. Howard might have told them. He was asked to castrate a three or four year old colt. It was a very vicious animal. It was got into a loose box and when Mr. Howard arrived there was not one about to help him. The owner went off to get help, the farm hands being at work at a place about a mile off. He was a long time away and when he returned he found that Mr. Howard had the animal castrated. That is only one case, but there are a great many others similar.

Mr. HARE thanked Mr. Howard for his excellent and interesting paper; he would like to support Mr. Howard in all he had said, but he had sometimes had cases which were not all plain sailing. He considered it the ideal method for castrating colts. He had experienced some difficulty at times in getting the muzzle on. Some thoroughbred colts will fight freely with their fore feet and rear, but after getting the sponge introduced there is usually no further trouble. He considered it most important that the colt be not allowed to get up too soon after the operation, as he had seen one or two cases of hæmorrhage which he attributed to this. With older horses he would prefer to cast first before giving the chloroform. With colts his experience is that some stand quite still after the sponge is introduced, until they begin to stagger and gently subside, others will walk or trot round, stepping very high. Sometimes they will run backwards, and then it is necessary to guard against their falling into a ditch; this is easily avoided by the man or men holding the rope attached to cavesson, manœuvring so as to get between the colt and the ditch. With regard to the muzzle, the one he uses is similar to Mr. Howard's, but has a perforated cap which holds the sponge in position. He thinks the perforations are a mistake, as the colt gets too much air and there is a waste of chloroform. For firing, he always casts before administering chloroform, but he will certainly give Mr. Howard's method a trial in this respect.

He was greatly impressed with Mr. Howard's paper, coming, as it does, at a time when this matter is being brought so forcibly before the profession.

Mr. MAHONY: I must join with those gentlemen who have already spoken in thanking Mr. Howard for bringing forward such an able and interesting paper; we are all very much interested in it. I have used chloroform and I must confess that I have always found a certain amount of excitement before the horse went under. Some time ago I had a conversation with Mr. Howard about giving chloroform standing, and as I always value very highly any advice coming from him, I determined in giving it standing. I had an opportunity shortly after in trying it, and I must say the method strikes me as very simple; as Colonel Moore stated, the animal sits down on its haunches, and there is not much trouble in getting him down completely. I may say that I cast one animal in a large box without any difficulty. I agree in giving a good dose to commence with; I find there is

less excitement as the animal goes under the influence immediately. The hobbles should be put on when the animal is down, as there is a certain amount of risk putting them on before the administration of chloroform.

Prof. O'CONNOR: I wish to thank Mr. Howard very much for his excellent paper. I heard that Mr. Howard was a past master in the art of administering chloroform in the standing position, and I thought it would be a splendid idea to get a paper from him on the subject. I am very glad he acceded to my request to give us one. I would, of course, prefer to see a practical demonstration of the method, and I think we may be able to arrange for one later on. I administered chloroform standing several years ago to a horse that I was about to destroy. I used a modification of the Carlisle muzzle, and gave about 4 or 5 oz. of chloroform. The animal went under it almost immediately and dropped to the ground completely anaesthetised. Recently I adopted this method for horses about to be operated upon, and found it did not answer so well. In one case the horse became terribly excited, reared, buck-jumped, and lashed out, clearing all the students out of the operating theatre. I feared that he might go through a window. We thought it safer to cast him before going further with the anaesthetic.

In another case the horse, after getting the muzzle on, persisted in rearing and striking out with the fore-feet when any person approached to put more chloroform in the muzzle. In this case also I considered it better to cast the horse at once with the ropes. In a third case the horse meandered about for a long time before falling.

But I believe the explanation of these apparent failures is that the dose administered at first (2 to 3 oz.) was too small, and that sufficient air was not included.

In each case I had a rope about 60 feet long tied at its middle part round the horse's neck, and held on either side by assistants to control the animal and prevent him going too much one way or the other. I would be afraid to try this procedure in a loose box for want of space, and for fear that the horse might fall in some awkward position, or injure himself against the manger.

When about to destroy a horse for surgical demonstrations I give an intravenous injection of a solution of about $\frac{1}{2}$ -oz. of chloral hydrate, and the animal goes down completely anaesthetised almost immediately. The objection to adopting this method in other cases is that the chloral is likely to cause phlebitis. I may say that an excellent way of destroying cats and dogs is to pour a little chloroform into the nose. It causes death in a very short time, much more humanely than by prussic acid, there being no spasms which are so unpleasant to observe in death from prussic acid.

Mr. MACCANN: As one who gives chloroform standing for the purpose of castration, I can speak from practical experience. Those who are opposed to or are sceptical about the method have either been scared after their first attempts or been afraid to experiment so as to get a proper average amount of chloroform. At first I used an insufficient dose and the results were not satisfactory. There was a distinct stage of excitement, and anaesthesia was not complete. I only used one and a half ounces. Later I increased to two ounces, for the yearling, and found that a couple of minutes after the sponge had been inserted into the muzzle the colt was ready to go down. Some colts stand stock still. Some trotted round with exaggerated action like, that of a hackney; while others walked backwards or forwards a few steps; gradually they lose balance and sit down on their haunches, when a little push sends them over.

With regard to catching the colt, the method I adopt is that suggested by Mr. McKenny. Having got the colt into a stable, I take one end of a long rope, an assistant takes the other end: one goes on each side; the rope is carried up along the colt's back and over

the neck. The two ends are then joined and twisted until tight. Get a man to hold the tail, that generally "knocks the stuffing out of him." In most cases the greatest difficulty is experienced in getting on the muzzle. The muzzle I use is Cox's, with a rope attached to the head collar, there is little difficulty in taking him to the field. Once there, I get the colt into the centre of the field; the assistants get round him. The sponge, wrung out of hot water, is saturated with chloroform and inserted into the muzzle. I have explained the course of subsequent events. I find that the shock of the chloroform knocks all the fight out of the horse: I never saw a colt become excited after I had used the proper amount.

When the colts are regaining consciousness after the operation, I have the halter or head collar on so that they may be steadied on rising. After rising they are inclined to wobble a bit. I have never had a colt gallop away after getting up.

Mr. Howard is to be congratulated on his paper, and the valuable information which he has placed before the meeting.

Mr. REAVY: I wish to join with the previous speakers in thanking our President for his very able paper. I have no practical experience of chloroforming standing, but I would like to ask Mr. Howard if he finds that thoroughbred colts are worse to handle than colts of other breeds. I would imagine that a heavy horse would go under quicker than thoroughbred colts. With reference to the case of death from heart disease—it is a good many years now since I was in college, but we were always taught to examine the heart before giving an anaesthetic.

Mr. HENEY said the discussion had been most interesting. This year, during the castration season, he was called upon to operate upon a four year old horse that had served 21 or 22 mares last year, he was a big, plain, useful sort. He administered chloroform standing, the operation being performed in a paddock, using a muzzle somewhat similar to that shown by the President—giving about three ounces, he had no trouble with the horse, going down quietly just as had been mentioned by Mr. Howard and others to-night; there was no trouble in controlling him, and he has worked well ever since. As regards Prof. O'Connor's method of destroying small animals by pouring chloroform down the nostrils, I have never adopted such a course, but I would commend him the use of hydrocyanic acid (Scheeb's) injected into the thoracic cavity, which is almost instantaneous in action. The use of chloral hydrate, in many cases, I have found more satisfactory than chloroform from the point of view that there is no excitement nor bad results. I tender to Mr. Howard my hearty thanks for his interesting practical paper.

A MEMBER: The only experience I have of chloroform being administered to horses standing was as an onlooker. I happened to be in London recently and at a yard there I saw it being administered to a horse. The box was lined with cocoa matting. There was a halter on the horse and ropes by which he was prevented from going too far forwards or too far backwards, and with the way the horse was being controlled by the ropes I saw there could not possibly be any accident. I did not wait to see the operation.

Mr. HOLLAND: Before calling on Mr. Howard to reply, I also would like to thank him for bringing forward such an excellent paper. It has given rise to a lively discussion. Mr. McKenny has some doubt about the excitement, but I think Mr. Howard made it clear that in some cases there was a little excitement. I want to make a remark in regard to the purchasing of chloroform. Messrs. Duncan and Flockhart give two forms of it, one in a blue labelled bottle at a lower price, which I find is equally as good as their other. I have implicit confidence in Mr. Howard, and when he made

the suggestion to me about chloroforming standing I adopted it immediately. I met two cases where there was excitement. Mr. Howard also explained to me that it was best to use a double rope and to manœuvre the horse into position. I generally put on hobbles when the animal is nearly under the influence, and when he is just about to fall, pull him down. Mr. Hare speaks about horse galloping away and falling after getting up and the difficulty of getting the muzzle on owing to horse striking with the fore feet. I think that might be got over simply by covering the eyes before putting on the muzzle, and by leaving the eyes covered until you are satisfied that the animal is safely from under the influence; he will lie quietly and be able to stand all right when allowed to rise.

So convinced am I of the necessity of conserving our interests in these days of wholesale quackery, I am a little discreet when using chloroform, and label it so that I may not enlighten every onlooker as to what the bottle contains. I generally use the small bottles, and I find them sufficient, and they give better results than if you purchase chloroform in large quantities. This paper which Mr. Howard has contributed is only one more to the many benefits that he has conferred upon this Association, not alone since he became its President, but also during his many years membership. (Applause).

Mr. HOWARD, in replying to the discussion, said: I have first of all to be very grateful for the hearing that you have given my paper, and the words of appreciation which have been spoken for my bringing forward the subject. It has been a great pleasure to me to bring it forward. I should like to remind you that this is not the first occasion on which I have discussed with you this question of the administration of chloroform standing. A few years ago I gave you statistics relating to the number of cases. As regards Mr. McKenny's experience, the men, he tells us, ran away and left the door of the box open, and the horse got out. Well, what did they expect? Medical men, when administering chloroform to a human being, see that he is under proper control. He is either strapped to the bed or to the operating table, and if that is necessary in the case of a human being, is it too much to expect that in the case of the lower animals care will be taken to see that the patient is not allowed to go and destroy himself. About this stage of excitement—we know from the history of giving it to human beings that people under its influence act in a fantastic way sometimes. Mr. Winter asked me how I secure a horse when operating on the hock. My experience is that for most operations, including firing, you only want to hold up one of the legs, and then do whatever has to be done. For yearlings and two-year-olds you only want someone to hold the upper leg out of the way, unless you have some other method, or stand contemplating half-an-hour whether you will do the job at all or not. When Col. Moore started to speak, I thought I was going to get a slaughtering, but his experience practically confirmed what I had said. I don't claim to be the pioneer of giving chloroform to horses standing, but I do claim to be the first in Ireland to put on record the result of my work in this connection, and to come before this Association and give them the result of my experiences. My friend and pupil, Mr. O'Brien, has mentioned to you a case which I did not intend to refer to. A client of mine, Col. W., had a three-year-old colt. He was a perfect savage. The Colonel asked me to castrate, and I arranged to do him, and wrote telling him the day I would be in the district, and to put the colt in the house. He replied and told me that they had got the colt in the house, but had not been able to get a cavasson on him. The appointed day came, and when I arrived at the Colonel's there was no one there to help me, the farm hands being at work about a mile away. The Colonel

himself went off to get help, and as he was a long time away I began experimenting with the colt myself. He was in a box about ten feet square. A very small boy, a messenger, came along, I put a rope on the colt and gave it to the boy to hold outside the door. After manœuvring with a long stick I managed to get hold of one of the colt's ears, and put the muzzle on him. I gave him about three ounces, and he never moved until he lay down. I castrated him with only the little boy to help me, and when I was ready to go home the Colonel and the helpers arrived on the scene.

As regards the practice of operating in the house or in a field, some people still have doubts. They think there is danger in the box, but with even untrained colts there is practically no danger if you have a box 10 feet square, or one 10 feet by 12, provided, of course, you take reasonable precautions to have the colt under control.

A MEMBER: A box without a manger.

Mr. HOWARD: With or without a manger. In the springtime, when the ground is wet and the weather cold it is perhaps just as pleasant working in a box as in a soddened field or paddock. I am particularly pleased and delighted with the remarks made by some of the older practitioners, who are, I may say, disciples. Mr. Mahony and Mr. Holland, at my request, made the experiment, and they are so pleased with the result that they are going on with it. Mr. Nolans, of Birr, was asked by me to-day if he would go back to the old method of first casting a colt or horse and then giving chloroform. His reply was:—"You have been driving a motor car for some time, and you find it much quicker and easier to get through your work than driving a horse for 60 or 70 miles, would you go back to the old way? I would as soon give up my motor as return to the old method. I can get through my work much faster and with a great deal more ease." That, I think, is practical proof of the advantage of giving chloroform to horses standing. Mr. McKenny stated that I promised to give a demonstration at his yard and had not done so yet, and Mr. O'Connor also expressed the hope that I would give a practical demonstration. Well, if arrangements can be made, I shall be happy to give the demonstrations, but I won't guarantee anything, for the case that you would want to make a success of might be the one that would give you trouble. But my experience is that 95 per cent will give you no trouble.

There seems to be a great difference of opinion as to length of time which should elapse before a horse is allowed to get up. As a rule horses which go down quietly recover equally quietly. My experience is that five or six minutes is long enough to keep a horse down after the operation. The reason why Turko was destroyed by chloroform was at the request of his owner. Turko was the property of Mrs. —, and she requested that he should be destroyed that way. I never gave chloroform to a horse before for the purpose of putting it out of this world, and I approached the task with some misgiving. I gave him four or five ounces before he went down, and he consumed eleven ounces before he was dead. Therefore there is not much danger in giving a strong colt three or four ounces.

Then, as for the danger of excitement which exists in some people's imagination, we all know that some people will talk and even lecture on subjects, but if they had to put their own theories into practice they would not make much of a hand of it. The reason why some people talk about excitement is, they have heard of it, but they have no practical experience in giving chloroform to horses standing and have not courage enough to persevere until they have overcome the difficulty. I thank you, gentlemen, for your kind attention.

Mr. McKENNY proposed a vote of thanks to the essayist for his paper. Mr. Howard himself and Col. Moore both said there was no danger in giving chloro-

form to horses standing, and yet they always take precautions against risks. The result of the discussion and Mr. Howard's reply shows that in some cases there will be a stage of excitement.

Mr. REAVY seconded the motion, which was passed unanimously.

On the motion of Mr. Mahony, seconded by Mr. Winter, a vote of thanks was passed to Mr. Holland for presiding.

The proceedings then terminated.

J. J. O'CONNOR, Hon. Sec.

LINCOLNSHIRE AND DISTRICT VETERINARY MEDICAL ASSOCIATION.

A meeting was held at the Albion Hotel, Lincoln, on Thursday, October 9. The President, Mr. C. W. Townsend, F.R.C.V.S., of Long Stanton, Cambs., in the chair. Also present: Messrs. T. B. Bindloss, Long Sutton; R. W. Clarke, Wragby; W. W. Lang, Ulceby; D. Cooper, Saxilby; C. Hartley, Lincoln; T. Hicks, Sleaford (hon. sec.); A. J. Hines, Grimsby; T. J. Keall, Gainsborough; A. D. Lalor, Sleaford; Geo. Lockwood, Peterborough; H. Leach, Boston; A. R. Routledge, Louth; T. A. Rudkin, Grantham; H. C. Taylor, Caistor; and H. P. Lewis, M.R.C.V.S. (Assistant Veterinary Inspector, Sheffield), who had kindly promised to give a demonstration on tuberculosis in carcase and in milk.

Apologies for absence were received from Messrs. A. Comerford, W. W. Grasby, F. L. Gooch, Abbots, B. A. Searby, of Ramsey; and Hy. B. Eve, of Folkestone, a former member, who sent photographs of tuberculosis in the udder and in various forms.

The PRESIDENT said that he felt sure it was the wish of the members present that the Secretary should write Mr. Eve acknowledging the photographs, and thanking him for his kind wishes for the meeting, and also for so kindly sending the photos.

Mr. HARTLEY apologised for the absence of his son, who was ill in bed with influenza.

The PRESIDENT said he knew it would be the wish of the members to convey to Mr. Hartley, jun. their sorrow at his illness, and to express a hope for his speedy recovery.—Mr. Rudkin seconded, and it was carried.

Mr. LANG, of Ulceby, an old member who had been to Wales and come back to Lincolnshire, was re-nominated by Mr. Tom Hicks.—Mr. Cooper seconded, and Mr. Hartley supported the nomination.

INSURANCE COMPANIES FEES.

The PRESIDENT said this matter was brought up at the last meeting, and he might say that from a meeting in London which he attended on the subject, at which a deputation was appointed to wait on the managers of the principal Insurance Companies, nothing definite had resulted at present. He did not think they could discuss it until after their Secretary had heard more about the matter, or in other words he himself thought the matter might rest, pending the result of that deputation.

Mr. RUDKIN proposed that it be left over until the deputation had reported.

Mr. CLARKE seconded, but thought the deputation would do more harm than good because the Insurance Companies could not afford to pay more, and they were taking animals without examination, and practitioners were losing the small fees they had been formerly getting.

The PRESIDENT: Yes, but for animals insured for £400 or £500 they certainly should give us a larger fee than we are at present getting.

Mr. RUDKIN: They cannot afford much for a £40 mare.

Mr. HARTLEY: For a £40 or £50 animal I should accept the present fee, but where an animal is valued at £400 or £500 I should expect more.

VETERINARY INSPECTORS' SCALE.

The Hon. Sec. said that Mr. Theo. C. Toope, of Dover, the Secretary of the Southern Branch N.V.A. in his letter to him, said:—

"I also note a scale of fees to veterinary inspectors published in last week's *Veterinary Record* as paid in the Holland division of your county. Surely this cannot be in force? They are, as reported, about the worst in England, and a disgrace to us."

Mr. BINDLOSS: We are paid on the old scale, 5/-, and 3d. per mile, and I have to carry a Police Inspector with me.

Mr. RUDKIN: You cannot hire anything for 3d. a mile.

Mr. BINDLOSS: And our inspector weighs 18 stone. (Laughter).

Mr. ROUTLEDGE: They only pay us 3d. per mile.

Mr. HICKS: I get 1/6 with the inspector.

Mr. HARTLEY: There is a new scale coming out for the Lindsey Division. Threepence a mile ought not to be accepted.

Mr. RUDKIN suggested that a letter should be written to the Clerks of the Holland and Lindsey County Councils calling their attention to the inadequacy of the fees paid under the Tuberculosis Order.

Mr. HARTLEY: Lindsey are suggesting two guineas for an examination, and a mileage of 3d. for every mile completed. That is inadequate.

Mr. RUDKIN: Threepence is ridiculous. You cannot hire a dog cart for that.

The PRESIDENT: In the County of Cambridgeshire we appointed a deputation to meet the Executive Committee, and after pointing out the amount of work and responsibility we incurred in carrying out the duties of the Tuberculosis Order and other contagious diseases they gave us practically all we asked.

After further discussion, it was decided that the Hon. Sec. write to the Clerks of the Lindsey and Holland County Councils pointing out the inadequacy of the fees and rate of mileage, and asking for the adoption of the scale agreed to by the National Veterinary Inspectors' Association, and which appeared in *The Veterinary Record* for May 3rd last.

PRESIDENTIAL ADDRESS.

Mr. C. W. TOWNSEND, F.R.C.V.S.

Gentlemen,—When at the annual meeting of this Association in February last, the members present bestowed upon me the greatest honour it was possible for them to confer upon any member of this Association, I must confess that your kind invitation to fulfil this position came upon me as a great surprise. Although it falls to the lot of the majority of the members of a veterinary Society to occupy, at some period of their membership, this honourable position, yet I can conscientiously say that I thought the time was far distant when I should be the one chosen to fulfil this post of President of your Association. Since you have elected me as your President for the ensuing year, I can assure the members that in carrying out any duties entrusted to me I should do so to the best of my ability, and I trust that in occupying the position of President the members will accord to me that same support and kindness which they have shown, not only to my predecessors, but also to myself for the past four years in the post of Secretary.

In addresses of this kind it has been the custom in recent years to make a few remarks upon the more important present day topics relating to our profession; before doing so, however, I would like, with your permission, to make a few remarks upon the affairs and past doings of this Association.

Having had the pleasure of acting as Secretary of your Association for the past four years, and having been a member for eleven years, I may say that during that time I have watched the progress made, and also taken great interest in the work done by this Association. I well remember at an annual meeting, held some four years ago, there was much discussion as to whether this Association should continue or not, the reason of this being not the dearth of existing members, but because of the few number of veterinary surgeons who attended the meetings, and the consequent lack of interest shown. For some reason we used then to see the same members present continually at each meeting, whilst on the other hand several members seldom or never put in an appearance—a state of things which did not tend to make the meetings very attractive, nor was it encouraging for those who regularly attended.

There certainly may be occasions when one cannot possibly get away from home, but since only three meetings are held in a year, I do honestly think that each member might, with very little effort, get to at least one meeting every year. However, gentlemen, I am very pleased to say that the attendances at meetings held recently have very much improved—a condition which I trust will continue to exist. I hope, also, that the membership of our Association, which now numbers nearly fifty members, will, with the co-operation and help of each individual member, also continue to increase year by year.

There are, no doubt, many ways by which not only can each member greatly assist in making this Association successful, but, each member can also contribute considerably in making our meetings enjoyable and attractive—perhaps most important of all is, by regularly attending the meetings. There also seems to be a slackness on the part of members of contributing papers, and I hope that a hint in this direction will have the desired effect, and so make the work of our new Secretary somewhat easier.

I think each member might do his best to obtain new members from the particular district in which he resides; I myself would like to see more Veterinary Surgeons of this County join our Association, for when one looks through the list of our members, only about one-half reside in the County of Lincolnshire—a fact much to be regretted.

Clinical specimens and cases of interest should always be brought forward whenever possible. These not only add to one's knowledge, but generally give rise to a discussion from which we can learn something useful to us in our every-day work. Speaking of discussions, I hope each member will, whenever possible, contribute to them, relate his own experiences, and express his opinions upon the subject chosen. This not only will add to our own knowledge, but it will also tend to make our meetings more sociable and enjoyable for all, and will help to promote that good feeling and fellowship which is one of the chief objects of our Association.

I would like to remark upon a few of the more immediate topics relating to our profession, although it is impossible in an address of this kind to refer at length to any except those that concern us closely at the present time. Perhaps the chief topic which is occupying our minds just now is the Tuberculosis Order. Since the report by the latest Royal Commission on Tuberculosis proves that the bovine type of tubercle bacilli is undoubtedly the cause of certain cases of tuberculosis in the human subject, it is hoped, that by carrying out this order that we shall, in the course of time, assist consider-

ably in reducing the mortality, and the frequent disability and disfigurement that this type of the disease causes annually in the human subject.

In carrying out the duties of this Order, there is no doubt that a considerable amount of responsibility is placed upon us, but I vouchsafe to say that the veterinary surgeon of the present day is eminently fitted for carrying out the duties in connection with stamping out this and other contagious diseases. Our past record in exterminating contagious diseases, when we have been given an open hand, fully justifies me in making this statement, and this new Order should further enhance our reputation with agriculturists and the public generally.

As the Order at present stands I, personally, do not think it will entail a great amount of work on our part—this has been my experience in connection with the amount of work I have had since the Order came into force, for although the Order only includes two types of the disease, I think we may rest assured that the Order will not remain as it now stands very long. Further clauses and restrictions will no doubt be forthcoming, and in conjunction with the work, that the Milk and Dairies Bill will, in time give us, must increase considerably our work before many years.

A suggestion has on more than one occasion been put forward that the duties of this Order, and in connection with other contagious diseases, should be done by all time men; I certainly fail to see why this should be the case. I am strongly of opinion that the curriculum and teaching of the present-day student renders him fully competent to carry out any work of this kind. In fact, when public health work is concerned, I maintain that no one is better fitted to carry it out in safe-guarding the spread of disease from animals to man than the veterinary surgeon. Moreover, a neighbouring veterinary inspector coming into one's private practice does not, in my opinion, tend to add to our reputation in the eyes of clients, and I think that each veterinary surgeon should have his own share of the work, both in carrying out this Order and other duties met with in connection with outbreaks of contagious disease.

The Amendment Bill is an important measure that has for some time engaged the attention of our profession. Although there has been a good deal of opposition to certain clauses contained in the Bill, yet, I think at the present time the great majority of us hope that the Bill will eventually become law. Not only must this Bill benefit us in several ways, but until this Bill is passed, or the College by some means put on a sounder financial basis than it is at present, we, as veterinary surgeons, cannot hope to get that advice and assistance in those important matters from the Council we would like to have.

Speaking of financial assistance, I certainly do think that the Government of this country might not only assist our College financially by making increased grants, as is done in other countries, but that they might also give greater financial assistance than is at present given in carrying out research and other work. Not only agriculturists but the country as a whole would be benefitted thereby.

The Animals Anæsthetics Bill is another important measure that is before the profession and has been discussed at considerable length in our weekly journals, in which discussions, I must confess, I was one of the first to take part. I still strongly maintain that before such a measure as this was brought forward its promoters most certainly ought to have sought for advice, either from the Council of our College or from some of the prominent veterinary practitioners. The Bill as at present drafted certainly seems to me to be a much more rational measure than it was when first brought forward, but it still requires modification before it will meet with my favour.

I take it, gentlemen, that as a profession, we consider it our duty to alleviate the suffering of dumb animals whenever possible, and we, by experience, should know when it is necessary to administer an anaesthetic or not in any operations we are asked to perform. I maintain that if this Bill is passed, as no doubt it will be at some future date, even in those operations included under the Bill, the veterinary surgeon should, in certain instances, be allowed to exercise his own discretion as to the administration of an anaesthetic.

The International Congress of Veterinary Surgeons, as you are all aware, is to be held in London next year. In carrying out the duties entailed by the holding of this Congress much work has to be done, and much money is needed. Other countries have, we are told, subscribed and made grants towards carrying out the work of this Congress when it has been held in foreign countries. Our own country is not so fortunate in this respect, and as a profession, and as Englishmen, we, I feel sure, will not be behind other countries in making the Congress as successful as it has been when held elsewhere. I hope, therefore, that each individual member of this Association will do his very best by subscribing towards the funds of this Congress.

As regards the future of our profession and the work done by the veterinary surgeons at the present time, I think we all agree that the work we are now called upon to perform is of a totally different nature from what it was twenty years ago.

Several factors are responsible for this change; perhaps the most important is the advancement of education. The knowledge possessed by the general public at the present time, both in the trivial ailments of animals and in matters connected generally with the prevention of disease, is considerably greater than it was even a dozen years ago.

Again, outbreaks of disease are much less frequent than they were; this, I consider, is chiefly owing to improved sanitation. Many of those contagious diseases which were rampant years ago are now exterminated owing to our increased knowledge and skill—a fact which we should be proud to relate.

Advance in motor traction has already diminished, and no doubt will continue to diminish the number of horses required for heavy traction work, and this is a serious factor to be reckoned with where town veterinary surgeons are engaged.

I have mentioned merely a few instances which suffice to show that not only has the nature of our work changed considerably, but that where the services of the veterinary surgeons were at one time frequently requisitioned, they are now no longer required. On the other hand, one must agree that although the nature of our work has changed, and in many ways decreased, yet, fortunately for us, it has in several ways increased. Perhaps no other branch of work in which the veterinary surgeon is now engaged, has made such rapid progress as the practice of canine and feline surgery, which now forms a considerable part of our every-day work.

We also gladly welcome the increasing recognition by the public of our services in any work in connection with public health, and I may here say that the recently passed Tuberculosis Order gives us yet another opportunity of demonstrating our abilities in this direction.

The improvement in the breeds of pedigree stock is a matter that should concern us, for I understand that appointments have recently been made in this branch of work.

I understand, also, that the number of graduates annually entering our Colleges is on the decrease, a fact that must in years to come make more work for the present veterinary surgeons.

Other branches of work which I have not yet mentioned must in time form a considerable part of our daily work; particularly would I like to mention the

subject of meat inspection, for although in my opinion this work should be carried out only by veterinary surgeons, I am sorry to say this is frequently not the case. However, we hope the time is not far distant when each town will have not only its own Public abattoir, but also its own meat inspector, for I consider that the knowledge and teaching of the veterinary surgeon at the present day renders him specially fit for undertaking this work.

I think, gentlemen, from the remarks I have made we may conclude that although our outlook is perhaps not so good as it was some years ago, yet it is not so bad as we are frequently apt to think it is; therefore, although our work has changed, and in some ways diminished, yet we should be thankful that it has increased, and we trust will still continue to increase, in many others.

Mr. HARTLEY moved, seconded by Mr. Taylor, that the President be cordially thanked for his address, and he felt sure it was the wish of the members present that it should be placed on the minutes of the meeting and duly published.

Mr. RUDKIN had much pleasure in supporting Mr. Hartley's resolution.

DEMONSTRATION ON TUBERCULOSIS

By Mr. H. P. LEWIS, M.R.C.V.S., Sheffield.

The PRESIDENT said that before adjourning to Mr. Hartley's yard for the demonstration, he would like, on behalf of that Association, to thank Mr. Lewis for so kindly coming there that day, especially would he himself like to thank him for coming there at such a short notice. Perhaps the members did not know, and he would therefore like to inform them that only three weeks ago their Secretary wrote informing him that he had no promise of any paper for the present meeting: so therefore the members must think themselves very lucky in obtaining the services of Mr. Lewis when such short notice had been given him.

Mr. HARTLEY: I would like to ask who obtained the services of Mr. Lewis.

The PRESIDENT: I think, sir, I may take the credit of having done this, or perhaps I ought really to say that our Secretary wrote Mr. Lewis, but it was at my suggestion, and I may here say I was put into communication with Mr. Lewis through Prof. Reynolds, of London.

Mr. HARTLEY: I think it was very good of you to do this.

An adjournment was then made to Mr. Hartley's commodious premises, where Mr. Lewis gave a most interesting and instructive demonstration upon the examination of milk, and also showed the members the position and relation of the common tubercular lesions met with in tuberculosis of the pig.

The following is a synopsis of Mr. Lewis' remarks.

Collection of Samples of Milk. The greatest care should be taken to ensure that the bottles and instruments which have to come in contact with the milk should be sterile before use. Corks should be good fitting and preferably rubber. The udder should be wiped with a cloth damp with some antiseptic solution. The sample bottle should be held, and the milk drawn into the bottle in the manner illustrated, and minimise the possibility of introduction of dried faecal matter detached from the udder. The importance of careful attention to the foregoing will be appreciated when it is realised that the chief source of error in diagnosis is likely to arise from contamination of the milk, as there are several known acid-fast organisms other than *B. tuberculosis*, but which are not pathogenic to the cow, and therefore only gain entrance to the milk when contamination has taken place.

Preparation of the Film. Considerable attention must be bestowed upon the preparation of the film. It is important that films should be thin in order to minimise the time necessary for decolorization. It is true that the tubercle bacillus will usually retain the fuchsin stain after a lengthy exposure to the decolorizing acid. Cases of tuberculosis of the udder are not infrequently met with, however, where the disease has been in existence a considerable time, and for which a strain of tubercle bacilli of low virulence is responsible. In such cases the bacilli may be partially or completely decolorized if subjected to the prolonged action of strong acid.

Opinions are divided as to the best method of preparing the film, and at the present time there are several methods in use. I intend to describe briefly two methods which are in more general use, and to give you an illustration of a third, which I have myself adopted for a number of years with very great success. It has advantages over the others in that it is simpler, less expensive, and gives more accurate results. It also takes up much less time, and it is seldom necessary to use a centrifuge.

The first method to be described is that in which a bleaching agent, known as "Antiformin" is used. This agent owes its action chiefly to the chlorine it contains in the form of chlorinated soda. The chief object to be gained by its use is the destruction of all acid-fast bacilli which may be present in the milk, with the exception of *B. tuberculosis*. A portion of the milk representing 35 parts, is added to 15 parts of "Antiformin," and 50 parts of distilled water. The mixture is then agitated for a few minutes, and afterwards centrifuged, or allowed to stand for an hour or two. The sediment is then transferred to the glass slide and fixed. Considerable care and attention is required in the fixation, otherwise portions of the film are washed off in the subsequent process of staining and decolorising. The film is afterwards stained in the usual way.

The second method is a modification of the preceding, and consists in the addition of a portion of the milk representing two parts, to one part "Antiformin," and agitating the mixture for five minutes. To the above mixture is next added Methylated aether and Acetone, in equal quantities representing one part. This mixture is again agitated and allowed to stand until there is a division into three distinct parts. The middle layer is a whitish opaque liquid, and is said to contain the bacilli in large numbers. A portion of this layer is pipetted off, and transferred to the slide. Fixation and staining is then carried out as in the previous method.

Mr. Lewis next illustrated another method by preparing a slide from milk which he had obtained from a case of tuberculosis of the udder; the various stages were described in detail. During the time occupied by the Ziehl-Neelson staining, some of the characters of tuberculous milk were discussed, and as the sample under examination clearly showed, such milk was not always of a watery character; on the contrary it appeared to be abnormally rich in cream.

The slide having been finished was then examined microscopically by the members, tubercle bacilli being plainly demonstrated.

Mr. Lewis also brought for inspection about three feet of the small intestine of a cow, showing numerous tuberculous ulcers; microscopic preparations from the ulcerated bowel, and of bovine tuberculous sputum were also exhibited.

The members were afterwards shown over the lymphatic glands in the carcase of a tuberculous pig.

On returning to the Albion Hotel, Mr. Hartley proposed a vote of thanks to Mr. Lewis for his kindness, and the ability he had shown; the demonstration had been most interesting.

Mr. GEO. LOCKWOOD seconded, and said that at the same time he would like to thank Mr. Hartley for the use of his commodious premises.

Mr. HICKS seconding this, both votes of thanks were adopted.

Mr. HARTLEY, in reply, said his premises always had been, and always would be, at their disposal. A little practice was always a good thing, and created interest in their meetings.

Mr. LEWIS said he was never more happy than when giving assistance to his colleagues, and he hoped to be present at the Lincolnshire Association's meetings again.

Before dispersing, the President said he would like to inform the members that at their next meeting, which was the annual one, and which, as they knew, would be held at Grantham, Prof. Reynolds, of London, had very kindly promised him to give a surgical demonstration upon some operation in the dog, and he hoped, therefore, as many members as possible would be present.

T. HICKS, Hon. Sec.

Royal College of Veterinary Surgeons.

SPECIAL MEETING OF COUNCIL.

A Special Meeting of Council was held at the Royal College of Veterinary Surgeons, 10 Red Lion Square, London, W.C., on Tuesday, Oct. 21st. There were present:—Mr. J. H. Carter, President, in the chair; Messrs. Banham, Barrett, Col. Sir F. Duck, Dr. McCall, Sir John M'Fadyean, Messrs. Mulvey, Price, Maj.-Gen. Pringle, and Mr. Fred Bullock, Secretary.

The minutes of the previous special meeting were read and confirmed.

The SECRETARY announced that letters of apology for absence had been received from: Messrs. Abson, Dunstan, Hobday, Lloyd, Mason, Packman, Sir S. Stockman, and Maj.-Gen. Thomson.

Second Schedule. On the motion of Mr. Mulvey it was resolved—That the revised Second Schedule, as adopted at the special meeting of Council held on 10th October, including the consequential alterations to Bye-laws 53, 54, and 67 be confirmed.

Fellowship Degree. On the motion of the President it was resolved—That the revised regulations for the Fellowship Diploma, as adopted at the special meeting of Council held on 10th Oct., be confirmed, to come into force on the date of the obtaining of the new Charter.

Diploma in Veterinary State Medicine.—On the motion of the President it was resolved—That the regulations for a new Diploma in Veterinary State Medicine, adopted at a special meeting of Council held on 10th Oct., be confirmed, to come into force on the date of the obtaining of the new Charter.

Notices of Motion. (a) Mr. MULVEY gave notice that at the next meeting of Council he would move the following resolution, which had been suspended on the notice board on the 10th October:—

"That candidates presenting themselves for the First Professional Examination in, and after, December, 1915, be required to produce a certificate of having passed one of the preliminary educational examinations in accordance with the revised regulations of the General Medical Council, provided that, in the case of candidates whose educational certificates are dated earlier than November, 1914, the present regulations shall apply.

That Schedule I, as revised, be approved.

(b) Sir JOHN M'FADYEAN gave notice that, at the next meeting of Council he would move the adoption

of the following bye-laws, which had been suspended on the notice board on the 10th October :—

"53A. *Exemption.* Students who have obtained a Degree in Arts, Science, or Medicine of any University in the United Kingdom, or the Diploma of Licentiate of the Royal Colleges of Surgeons and of the Royal Colleges of Physicians, and who at the respective examinations for such degree or diploma, have passed in Chemistry, and also in Biology, Zoology, or Botany, are exempted from attendance at the first year's course of lectures and from the examination at the end of that year, provided that each student so exempted shall be examined in the whole subject of anatomy in the Class B. Examination.

Students claiming exemption under this bye-law must submit to the Secretary of the Royal College of Veterinary Surgeons, not less than three months before they intend to present themselves for the B. Examination, satisfactory evidence that they are entitled to the exemption."

This concluded the business of the special meeting.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

WAR OFFICE, WHITEHALL, Oct. 21.

REGULAR FORCES. ARMY VETERINARY CORPS.

Maj. W. D. Smith to be Lieut.-Col., *vice* J. Moore promoted. Dated Oct. 15.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

V. A. Bartrum (late Sec.-Lieut. Welsh Border Mounted Brigade and T. and S. Col. A.S.C.) to be Lieut. Dated Oct. 22.

Personal.

HUNTING's condition has not improved during the past week. No operation has been attempted.

The Right Hon. Earl DERBY, G.C.V.O., P.C., D.L., has consented to accept the office of President of the 29th Congress of the Royal Sanitary Institute, to be held at Blackpool from July 6th to 11th, 1914.

In recognition of the services rendered by Sir THOMAS ELLIOTT to the agricultural industry during the many years he was secretary to the Board of Agriculture, it has been decided to entertain him to a dinner, and the Earl of Northbrook is making the arrangements. The dinner will be held at the Hotel Cecil on Wednesday, November 5.

OBITUARY

ALBERT INKERMANN DOUGLAS DRAKE, M.R.C.V.S. (late A.V.D.) Graduated, New, Edin: July, 1878.

Death occurred at Wells-next-Sea, Norfolk, on 19th October, from pulmonary tuberculosis. Aged 58 years.

[Name removed from Register in 1895, Section 5 (4).]

RICHARD GLOVER, F.R.C.V.S., Richmond House, Romford Road, Forest Gate, Essex. Lond: April, 1877.

Mr. Glover's death occurred on Sunday, 19th inst. His age was 69 years.

E. W. NICKSON, M.R.C.V.S., Blackpool, Lancs.

Livpl: Dec., 1904

Mr. Nickson died on Oct. 14th from rheumatic fever. Aged 37 years.

Mr. C. H. BROCKLEHURST, who was a frequent contributor to our pages some few years back, passed away at Ramsgate on Tuesday, 14th inst.

WILLOWS.—On the 20th inst., at his home at Hassocks, Sussex, at the age of 79, there occurred the death of Mr. Jesse Willows, for many years senior partner of Willows, Francis, Butler, and Thompson, at 101 High Holborn, and 40 Aldersgate Street. He retired in 1904, upon the business being registered as a limited company.

The late Mr. Willows worked his way by sheer hard work and sterling qualities, and richly deserved the success that crowned a strenuous business career.

In his private life he was one of the kindest-hearted and most genial of men, and was never happier than when showing hospitality to his many friends. His principal recreation for many years consisted in riding and driving; he was an excellent judge of a horse, and had some exceptionally good ones in his time.

Interment on 23rd inst. at North Mimms, Herts., in which parish he lived formerly for several years.

LAMENESS AND DIAGNOSIS.

Dear Sir,

With your permission, I venture to make a few further remarks on the above subject. The discussion, so far, has elicited some important points. I must thank "Anti-Humbag" for his criticism, and for bringing forward definite evidence with reference to the latent nature of some cases of navicular disease. Such facts open up an important matter in connection with the medico-legal aspect of the disease, as evidently it is quite possible to examine a horse as to soundness, and to pass him sound, yet at the same time the animal may be suffering from navicular disease in a latent form, and go lame within any time after examination.

When I used the term "early stage" of the disease, I meant to convey, the stage during which the lameness was not continuous, although during each attack the symptoms supposed to be characteristic of the affections, were present. This stage may be a very prolonged one, so that the term "early" is not correct. I quite admit that the opportunities for making post-mortem examinations at this stage are few and far between.

Mr. McKenny's remarks on "diagnosis" indicate that he does not think it desirable for practitioners to admit the limitations of their skill. He first gives his views on the use of the "first person plural," and seems to imagine that, when a writer employs such, lay readers will infer that said writer undertakes to speak for the "entire profession." I am afraid that he under-estimates the intelligence of the lay readers who peruse the columns of *The Veterinary Record*. I may remark *en passant*, that in the article for which I am responsible, the "egotistical I" is employed.

But one does not need to "read between the lines" of Mr. McKenny's letter to discover the direction in which he is aiming, although he writes in what the lawyers would term a "guarded" manner.

Being one of those who are described by Mr. McKenny as "lacking of the ability to apply practically, and to utilise the knowledge which is set forth as taught in the curriculum of our Colleges." I hope he will not consider it presumption on my part if I join issue with some of his statements.

It is comforting, at any rate, to know that even the above College teaching is not sufficient for a "diagnostician." So Mr. McKenny gives a vivid description of the physiological attributes necessary for the prevention of errors in diagnosis. Fortunately he does not say that the "erring ones" do not possess these attributes, otherwise they would feel deeply crushed (?)

It is really remarkable how anyone could "please to stultify himself by publishing his errors," or his "deplorable experiences." But still some of the highest medical authorities indulge in this pastime, and quite lately a lead-

ing article appeared in a medical journal on the object lesson to be derived from erroneous diagnosis.

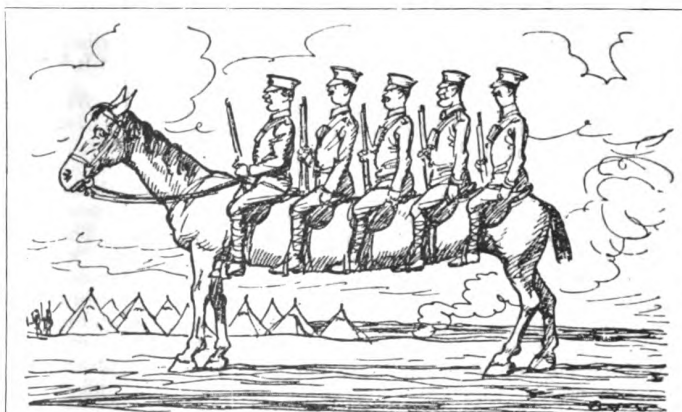

Evidently the medical profession are above the idea that "such conduct is a breach of professional etiquette, and certainly does not tend to inspire the public with confidence in the ability of the members of the profession."

The concluding sentence in Mr. McKenny's letter is remarkable. One would infer from it that typical symptoms were usually present, and that post-mortem results coincided in most cases with the diagnosis. What a Utopian state of affairs! Of course, it all depends on the practitioner; when possessed of all the attributes described by Mr. McKenny he cannot err, more especially *when in obscure cases he does not form a definite opinion*. Why go to the trouble of conducting post-mortems at all when a definite opinion has been given?

I fear that much of the self-confidence which "inspires the public" is possessed by those who do not make post-mortems on cases in which a definite opinion has been given. "A canty conceit of oneself," as they say in Scotland, is a very useful attribute.

As regards the "breach of professional etiquette," Mr. McKenny should certainly report the matter to the Registration Committee. Being such an upholder of a rigid code of ethics, his opinion would carry great weight with that august body.

"WE."

Dear Sir,

Mr. McKenny's remarks on the use of the word "We" and "I" remind me of a statement in an American paper "that the only persons entitled to speak of themselves in the first person plural are a reigning monarch, a newspaper editor, and a man with a tapeworm."—Yours truly, H.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1321.

NOVEMBER 1, 1913.

VOL. XXVI.

William Hunting, F.R.C.V.S.

Once more we have to chronicle the passing from amongst us of a valued member of the profession, and it falls to less able hands to do for him what he has done so often and so well for his brethren who have gone before. On every hand we hear the words "a loss to the profession." The strong, clear judgment, the unswerving devotion to the interests of the profession, the sound professional knowledge, the genial manner, and the charming, magnetic personality made him unquestionably the most popular man in the profession.

A strong advocate and a keen adversary, he enjoyed contest, and none who knew his powers entered carelessly upon a controversy with him. His reading was wide rather than deep—he was a practitioner, not a professor.

As a young man at Cirencester, he was an athlete and a boxer, and he carried with him through life the dash and vigour of those early days. Even to within a few days of his death, the old fire would show again when the haunting pain left him for a while.

He had little faith in the practice of therapeutics, and looked with doubting eyes on the host of new remedies which are continually produced. Yet he knew that mallein is, in careful hands, practically infallible, and that tuberculin is scarcely less reliable as a diagnostic.

Generous almost to a fault, few of the many who came to him in trouble went away unrelieved, and there are many who will miss him. The calls upon his wide experience by his professional brethren were numerous—and never in vain. His best was at their service, and if perchance he was unable to assist them, they knew it was not for want of will.

But to those who were privileged to know him in his home, the love borne him by his children told even more of the lovable nature of the man.

William Hunting inherited veterinary traditions, and passed the whole of his life in the veterinary atmosphere. For several generations before our Charter of Incorporation was granted, there were Huntings practising at Yoxford, in Suffolk. Charles Hunting, who graduated from Camden Town in 1850, was a descendant of these Suffolk practitioners, and the father of William Hunting. Charles Hunting went north and settled at South Hetton, in Durham, where he became a successful practitioner and a man of distinction within the profession. He was Vice-President of the R.C.V.S. in 1865, a Member of Council from 1866 to 1870, and was one

of the few members of the College who were elected Fellows under the Supplementary Charter of 1876. It was in his practice—a combination of the colliery and country practice—that the son gained his earliest professional experience.

William Hunting graduated in 1865 from the New Veterinary College of Edinburgh, which Prof. John Gamgee carried on in the Scottish metropolis for a few years, and afterwards for a still briefer period in London as the Albert Veterinary College. For the first few years after graduation, Hunting's career included assistantships with his father, with Mr. Greaves of Manchester, and Mr. Cartwright of Wolverhampton, and a professorship of Veterinary Science at the Royal Agricultural College, Cirencester. Perhaps the most important phase of this early period was his re-association with John Gamgee, who, in 1868, appointed Hunting to a professorship at the Albert Veterinary College, terminated soon afterwards by the closure of the institution. Gamgee, a man in advance of his time, lost touch with veterinary matters soon after the failure of his school; and, at his death in 1894, he was almost forgotten by a profession which had never recognised his worth. Hunting, who rose ultimately to a far higher position than Gamgee ever attained, never ceased to speak of his old master with admiration and affection.

Hunting then engaged in private practice in London, and in the seventies was one of the first to give serious attention to the diseases and treatment of dogs. It is of interest to note that, in 1877, he was one of the successful candidates at the first examination for the Fellowship Degree. About this time he was beginning to be known in and beyond the profession, chiefly as an advocate for the repression of glanders and rabies; but the limited opportunities of a working practitioner for some years hindered his advance in the profession.

In 1888 he founded *The Veterinary Record*, assuming work for which his natural capacity and life-long experience peculiarly fitted him, and meeting an urgent need in our professional life. After this, his rise in the profession was rapid. In 1890 he became a member of Council, and was largely concerned in obtaining the Supplementary Charter of 1892—thus taking a share in the repeal of the famous "Ninth Clause," the elevation of the students' matriculation into one worthy of a profession, and the establishment of the four years' course. He was President of the R.C.V.S. in 1894-5, and his work upon the Council closed in 1896. Subsequently he became an examiner for the Membership and Fellowship Degrees, obtaining

the appointments in 1898 and 1901 respectively, and retaining both till his death.

In 1907, Hunting relinquished his private practice and an extensive consulting one to become the chief Veterinary Inspector under the L.C.C. No one knew better than himself that the step was to his financial disadvantage; but his interest in the campaign against glanders impelled him to take it. Later, he exchanged this position for that of consulting Veterinary Surgeon to the L.C.C., thus regaining the liberty to practice as a private consultant. His connection with the L.C.C. only terminated under the age limit.

WILLIAM HUNTING—AN APPRECIATION.

The profession will have learned with the most profound regret of the death of our old friend, William Hunting. One may safely say without fear of contradiction that each of us has lost a friend, the profession as a whole a champion of its highest ideals. Inasmuch as William Hunting exerted so wide a personal influence upon us all, and was esteemed so very much by the whole of the profession, a mere official announcement of his death and work would not sufficiently indicate the love which was entertained for him, and the warmth of our attachment to him. Accordingly I pen this brief "appreciation."

What were the peculiar traits of character that so endeared him to us all? He was, first and foremost, forgiving and sympathetic to an extreme degree. Wholly incapable of revenge or ill will, one remembers him many years ago, when, robust of health and mental energy, he was in the thick of the fight in respect of questions which were at that time agitating the profession, full of fighting spirit, keen to carry his points, bitterly opposed, it may be, to many of his closest friends, and yet, withal, when the controversy was over, or a banquet on hand, exquisitely sensitive to the demands of friendship, and forgiving wholly those to whom but a short while ago he had been fiercely opposed. His frankness of character and guilelessness attracted most of us. He shook hands with you firmly and warmly, and looked into your face with honest piercing eyes that possessed that indescribable magnetic influence which drew you towards him. You felt that he was your real friend, one whom you could trust and rely upon, even though your opinions clashed, and your character, may be, was not at all in keeping with his.

All will, I know, agree with me when I add that he loved his profession and ever strove to exalt its social and scientific standing. As to the social aspect of his nature no professional dinner was a real success if William Hunting were absent. He seldom was! The function in his absence appeared to lack warmth and finish, and many a time when modesty induced him to refuse to speak to a toast, he was called upon just for a little speech. The annual dinner, but for him, would have ceased several years ago. He sought to continue it in order that little frictions, occasioned by a multitude of causes, might be effaced, and the professional horizon rendered clearer pending the advent of another storm. His view on the matter may be put this way:—"I think these dinners do a great deal of good; we invite men of scientific and social distinction to our feasts, and thus secure their goodwill and influence on our behalf, and we bring together our members who are too prone to drift apart and lose interest in the pro-

fession." His social work therefore clearly was done in the interests of the profession.

As to his scientific attainments, William Hunting would not desire that I should write of him as a profoundly learned man. He was too fond of literature, and had too much professional work on hand to study science deeply. To-day, the calls of science have become so exacting that, to become distinguished, one must devote one's whole time to the work. Hunting did not do this. He loved classical and social writings too much. Nevertheless, he was fully abreast of the times in relation to scientific discoveries, and through his journal frequently inculcated to his readers the necessity of the adoption of recent scientific innovations. He may be described as a somewhat prolific writer. Always clear and logical, the language was especially directed to the point sought to be elucidated, and conveyed his opinion with precision and force.

His book on Glanders is a recognised standard work, and denotes his gifts. His knowledge of this disease from a clinical and post-mortem aspect was remarkable, and one may truly say that the great diminution of glanders in London is due almost wholly to his influence and work. He desired, he said more than once, to live to see glanders exterminated from the metropolis. Alas, he has left us just too soon to see this achieved.

One cannot but feel that London horse-owners and indeed the public generally in its ignorance of the disease, and of the ravages it has effected in the horse and man, have not extended to him one tithe of the gratitude which was his due. Hunting's temperament needed little thanks to satisfy it. An achieved object, even though unassociated with wealth or honour, sufficed for his ambition. It is gratifying, however, to be able, personally, to testify to the esteem in which he was held by the London County Council during the period in which he acted as their Chief Veterinary Inspector. Mr. Ollis, his then chief, who has done such splendid work in the suppression of glanders, has more than once spoken to me in praise of Hunting's knowledge, and has acknowledged often how valuable his advice was when difficult questions as to administration arose. As an officer of that body, possessed of wide powers, he was, although assiduous in effecting his purpose, ever kind and considerate to those who necessarily suffered by reason of his orders. Hence it was that horse-owners with animals affected with glanders resented in the least possible degree his intrusion into their stables. At the conclusion of his period of service for the Council, there were several of us who thought that his services might wisely have been retained as a consultant. Financial calls in other directions alone, however, precluded this, and the services of a really great officer in the end were unfortunately lost.

As a consultant, he was fearlessly called in by his nearest practitioner. One couldn't imagine Hunting ever after, attending for a man from whom he had directly, or indirectly, received a consultant's fee, and hence, partly, the frequent request for his services. If our work were of a nature to require frequent consultations, Hunting would have made his mark—and a large fortune. As a consultant, I often felt he was too doubtful of his opinion; the possibilities of other pathological conditions were always present to his mind, and he regarded diagnosis as an extremely difficult art. He impressed the client who was not quite behind the scenes, and relieved the practitioner of all anxieties as to his client, which, perhaps, till Hunting's arrival, troubled him more than the responsibility of the case. One can say this much, that he never failed to support his colleague and tide him over the difficulty.

As an examiner was he not ideal? I once saw him examining at Camden Town. Hunting sat upon a stool in the operating shed, smoking a cigar; he seemed

supremely happy. A student, who looked quite at home, was directed to point out the seats of certain operations. He made a mistake. "Nonsense man," says Hunting, "I am quite sure you know better; try again, and don't get flurried." "Ah, that's it. You are right now. I knew you understood the matter. But don't get worried." The student beamed upon him with gratitude, and appeared to say "how very kind you have been to me." When Hunting first introduced the cigar—and what cigars they were—during examinations a member of Council at next meeting, with the best intention in the world, questioned the wisdom of such a proceeding, but was appeased when someone observed, "Hunting must smoke whatever happens, and its only Hunting."

He was perhaps best of all in the witness-box. As an expert he was in much request. I came into contact a good deal with him in this connection. He mostly appeared in support of his professional brethren. I remember one case particularly. I appeared for a veterinary surgeon who was charged with cruelty; they fought the case most strenuously, and somewhat to my surprise Hunting stepped into the witness-box to give evidence for the prosecution. He was usually perfectly cool and collected. On this occasion, however, he appeared nervous and fidgety, and when I rose to cross-examine him he looked at me with partly diverted eyes. I knew his weakness when against a colleague, and after a time asked him if, apart from the opinion he personally held, he attached blame to the defendant in respect of his treatment and care of the patient in question? He answered "No, of course not, any practitioner might have acted as he did. I can only say what should have been done, and I am not necessarily right." The case was won, of course. Afterwards he walked away from the Court alone, appearing dejected and miserable. I called "Hunting, come and have lunch with me, and give me one of your big cigars to smoke after." We had lunch—and cigars, and travelled to town together, happy, as I felt, in each other's company. That was just Hunting. How many of those Corona cigars he smoked a week I don't know—his case seemed ever open to you.

Just one more characteristic. He was appearing for the defence in a cruelty case. The veterinary surgeon for the prosecution described rather minutely the condition of the animal, the subject of the charge. At the luncheon interval Hunting said, "Barrett, I can't support your case after that evidence, it would be wrong." I simply said of course not, we must escape on a point of law if at all; I won't put you in the box. I relate these two cases to show how loyal he was to his colleagues, how he loved to support them, how distasteful it was to oppose them; but more than this, when unable to give honest evidence he preferred to give no evidence at all.

Unmindful of a fee, I have often said: "Your fee must be so-and-so, not the sum you state. Your evidence has been of too great value for such small remuneration." Often he was not convinced. There was in him that indescribable something which attracted the Court. The judges frequently asked him questions, appeared always assured of his honesty, and often decided in accordance with his convictions. Some other clients were much attached to him. One client frequently attended our dinners on Hunting's invitation, and always took the opportunity when I spoke to him of speaking of his adviser in the highest esteem.

I cannot help feeling that in some respects Hunting mistook his calling. He, no doubt, was especially happy as a veterinary surgeon, and yet his literary gifts were of such a high order that in this sphere of work he would have achieved real distinction. His success of *The Veterinary Record* proves his merit in this connection. The publication of "The Record" has been an

immense boon to the profession. Many of the articles therein bear the stamp of his work. He did literary work for the real love of it, and was more deeply read in the translations of the classics than is generally supposed. It may not be generally known that he read largely works on political and social economy. I can imagine that if Hunting had lived in the 18th century he would inevitably have been drawn to those coffee houses of literary fame, and would have enjoyed the society of the remarkable men who so constantly frequented them.

It is, alas! all over so far as he is concerned—we all deeply deplore his loss. Fortunately his merits have in a small measure been recognised. There is hanging in the Council Chamber at Red Lion Square an oil painting of our old friend: we shall look upon it with sadness when we next enter the Council Chamber. It won't be William Hunting, it will lack the magnetic influence of his personality; the eyes suspended there will not pierce you with the vividness of his in life; the smile upon the countenance will lack the warmth that characterised his smile, nor will the lips appeal to us as his once did. Yet we would much prefer the lifeless image to nothing in remembrance of our lost friend, and feel grateful to those whose thoughtfulness and generosity have given us even this.

Each of us extends to Miss Hunting our deep felt sympathy in her irreparable loss. If we loved him so well as a colleague, how much greater must her love for him extend as a daughter. It is, I know, the earnest hope of the profession that, in some measure, our esteem for her late father will assuage the grief which his loss must have occasioned her.

We shall miss him sadly for a while, our banquets will lack originality, our meetings lose the charm of his presence. We must console ourselves so far as is possible by the philosophic reflection that all may be for the best, that the puzzle of life, though to us inexplicable, is well ordained by Him who counteth the sparrows as they fall and ordaineth the whole wonders of the universe around us. All, I know, will join with me when I say good-bye to our dear old loved friend, William Hunting.

W. FREEMAN BARRETT.

Fountain Court, Temple, E.C.

INTERNATIONAL VETERINARY CONGRESS, 1914.

A meeting of the Organising Committee of the Congress was held at the Royal College of Veterinary Surgeons, 10 Red Lion Square, on Friday, Oct. 10th.

Present. Messrs. Almond, Archer, Banham, Bullock, Carless, Carter, Clarke, Dunstan, Garnett, Hancock, Lawson, Litt, Locke, Prof. J. McCall, Dr. J. McL. McCall, MacCormack, Sir John M'Fadyean, McIntosh, Male, Prof. Mettam, Price, Maj.-Gen. Pringle, Prof. Reynolds, Lieut.-Col. Rutherford, Samson, Prof. Shave, Simpson, Slocock, Maj.-Gen. Smith, Spicer, Sir S. Stockman, Maj.-Gen. Thomson, Maj. Todd, Trigger, Villar, Wharam, Willett, Prof. Wooldridge.

Minutes. After reading the minutes of the previous meeting, the Hon. Secretary reported that he had received apologies for absence from the following: Messrs. J. Abson, W. Awde, H. Begg, J. J. Bell, P. G. Bond, W. H. Brooke, H. J. Dawes, Prof. Gifford, F. L. Gooch, W. W. Grasby, J. Henderson, F. T. G. Hobday, J. A. Jordon, L. W. W. Lloyd, J. S. Lloyd, A. I. MacCallum, J. Malcolm, S. J. Marriott, Col. J. Moore, A. T. Sewell, T. F. Spencer, C. Stephenson, J. A. Todd, C. W. Townsend, P. Wilson, W. Woods.

Army Representatives. The Hon. Sec. reported that he had received a letter from Maj.-Gen. Pringle nomi-

nating Cols. Rutherford and Butler, and Lieut.-Col. Moore to represent the Army Veterinary Service on the Organising Committee.

Correspondence. The HON. SEC. stated that he had received applications from non-professional gentlemen who desired to become members of the Congress. It was pointed out that by the standing rules only those persons who were elected by former Congresses on account of their scientific work were Honorary Members.

With regard to non-professional men it was pointed out that it was not usual to admit these as members of the Congress unless they were delegated by bodies qualified to do so.

Correspondence from certain scientific men of different countries proposing subjects for discussion which were not on the official programme was discussed. It was decided that the existing programme should not be added to, as it was likely to become overloaded thereby.

In consequence of the correspondence the question was again raised as to whether donations should be received from trading firms whose business interested them in veterinary affairs. It was decided that subscriptions to the organising fund should not be limited to members of the veterinary profession.

Hon. Secretary's Report of Progress. The HON. SEC. reported that the Board of Agriculture had communicated with the Foreign Office and the Colonial Office, and had suggested that invitations should be sent out. The following despatches had accordingly been sent from the Foreign and Colonial Offices:—

[Copy].

Downing Street, Sept 10, 1913.

Sir,—I am directed by Mr. Secretary Harcourt to acknowledge the receipt of your letter No. A.4359/1913 of the 30th July, on the subject of the representation of the British possessions at the International Veterinary Congress which is to be held in London next year, and to state, for the information of the Board of Agriculture and Fisheries, that a copy of their letter has been sent to each of the self-governing Dominions and States, to the High Commissioner of South Africa, and to the undermentioned British Colonies and Protectorates:—

British Guiana	St. Christopher-Nevis
Jamaica	Cyprus
Trinidad	Malta
St. Vincent	Nyassaland
Ceylon	Uganda
Straits Settlements	Sierra Leone
Malay States	Gold Coast
East Africa Protectorate	

Mr. Harcourt is also communicating a copy to the British South Africa Company.

I am, sir, your most obedient servant,
(Signed) H. W. JUST.

The Secretary, Board of Agriculture and Fisheries.

[Copy].

Foreign Office,
September, 1913.

His Majesty's Representatives, Abroad.

Sir,—I transmit to you herewith copies of the programme of the Tenth International Veterinary Congress which it is proposed to hold in London from August 3rd to 8th next year, with the request that you will communicate it to the Governments to which you are accredited inviting them at the same time to send delegates thereto.

The history of these Congresses is as follows:

Forty-nine years ago, at the suggestion of a distinguished British veterinarian, John Gamgee, the first International Congress was held. Gamgee's suggestion was put forward on account of cattle plague which had travelled from Russia practically all over Europe devastating the herds, and he recognised that the control of

animal plagues could not depend entirely upon each country itself, but must be the common care of all. The wisdom of Gamgee's suggestion was immediately recognised by all the European countries. These Congresses *inter alia* discuss all international questions in relation to animal plagues.

Arrangements could not, unfortunately, be made to hold the first or any of the other Congresses in Great Britain, but they have been by arrangement held every five years in various capitals of Europe—Paris, Brussels, Berne, Baden-Baden, and Buda Pesth. The Governments of the various countries concerned have always issued invitations to other Governments to send delegates.

The 9th Congress was held at the Hague in 1909, and on that occasion the Governments of Argentina, Austria, (including Bohemia, Croatia and Slavonia), Bavaria, Belgium, Bulgaria, Colombia, Cuba, Denmark, Germany (including Saxe-Weimar), France (including Algeria and Tunis), Greece, Guatemala, Hungary, Italy, Japan, Luxemburg, Mexico, Norway, Netherlands, Roumania, Russia, Saxony, Servia, Sweden, Switzerland, United States of America, Uruguay, and Wurtemberg were represented, as well as Great Britain and certain of the British over-sea Dominions.

Although the Congress is not promoted by His Majesty's Government, they take a great interest in the objects for which it is being summoned, and would learn with pleasure that the invitations had been accepted. They would also view with satisfaction the separate representation at the Congress of such educational, scientific, or other bodies in foreign countries as are interested in promoting the veterinary and kindred sciences.

The CHAIRMAN said that it was very satisfactory that invitations in the terms they had just heard read had been sent out. That was one of the difficulties in the way of having England selected as a place for the meeting of the Congress. The members of the Permanent Commission were averse to a Congress being held in any country in which it was not recognised by the Government of that country.

It was also stated that the Foreign Office had promised to give a reception in honour of those attending the Congress, and they were thus taking a real interest in the undertaking.

In reply to Mr. Carless, the Chairman stated that the Foreign Office would take no interest in financing the Congress, but in that they were not treating the veterinary profession any differently from the way in which other Congresses were treated financially. There was no precedent for the British Government giving a subsidy to any Congress of the sort.

The Hon. Secretary's progress report was considered very satisfactory.

TREASURER'S REPORT.

The TREASURER reported that new subscriptions had come in very slowly since the previous meeting. The total amount now promised was about £3,160; that was £320 short of what was required. They had set out to get £3,500, but as £500 of that was earmarked as a special reserve fund they could not call upon that unless the amount subscribed in the ordinary way was not sufficient to meet the expenses. They still required £320 in order to reach the minimum originally fixed. Death had carried off a certain number of those who had promised to subscribe. As he had not received any answer to his requests for payment from certain members who had promised a subscription, he thought it possible that some of the promised subscriptions might not be forthcoming. A large number of the English veterinary surgeons had not yet subscribed, and he thought it would be well to make another appeal to those who had not done so. The veterinary societies

had in very many cases done what they could in the way of securing subscriptions, and it was to the credit of the smaller societies, and especially certain of them, that they had received the very handsome sum they had already in hand by promise. Some of the larger societies were still at work such as the Lincolnshire, Yorkshire, and the Central in London, and he thought they might hope to reach the original minimum, but he was forced to lay stress on the fact that they now knew there was every prospect of a much larger number of delegates and representatives being present at this Congress than at any previous Congress, and he was of opinion that the minimum sum fixed would be much too small.

The HON. SECRETARY stated that at a previous meeting the exceptionally large number of representatives expected at this Congress had been discussed, and in accordance with the directions of the Committee to extend the subscription list to all members of the Royal College of Veterinary Surgeons, whether resident in the British Isles or not, he had sent out a circular inviting subscriptions from all members in the British Colonies and other countries.

The HON. TREASURER stated that he had already received substantial subscriptions from some of the members of the Royal College who were resident elsewhere than in the British Isles.

Mr. DUNSTAN asked how many veterinary surgeons had promised to subscribe, and the Hon. Treasurer replied that he had not the exact figures, but the number was less than three hundred.

The CHAIRMAN stated that it did seem pitiable to think that only about three hundred out of some three thousand members on the Register had subscribed or even promised to subscribe to the Congress. It meant just one in ten.

The HON. TREASURER stated that unfortunately some members seemed to think that their obligations had been met when the Society of which they were members sent a subscription. He did desire to point out that that was not the case.

In reply to a question, the Hon. Treasurer stated that the amount of money actually in the bank was £1,050. He urged upon all members to try and get another ten to pay at least one pound each to the Organising Fund.

The CHAIRMAN suggested that it ought to be very easy to do that; more easy than to get ten men, as they had got, to give £100 each.

It was suggested that a further application should be issued by means of a letter from the President, in which it should be pointed out that the expenses of each individual member of the Congress would be about £3, and that the ordinary subscription of membership—one pound—would not cover it. [This was agreed to.]

Exhibits. The HON. SECRETARY asked for instructions with regard to exhibits, and it was decided that exhibits by manufacturing firms should be allowed.

Assistant Secretaries. The HON. SECRETARY asked for permission to appoint assistants to help him in his work and to add their names to the Organising Committee.

This was agreed to.

It was also agreed that the skeleton programme should be prepared and issued, together with forms for membership subscriptions.

Place of Meeting. The CHAIRMAN stated that it was very urgent that rooms should be engaged at once for the meetings of the Congress, or they might find it impossible to get a suitable place. He suggested that a Sub-Committee should be appointed to make inquiries, and to engage a suitable place or places for holding the meetings.

It was resolved that a small Sub-committee, consisting

of the Chairman, the Hon. Treasurer, and Secretary, together with Messrs. Willett, Price, and Wooldridge, be appointed to make inquiries and to engage the necessary rooms.

Reporters. It was also resolved that the Sub-committee appointed to select scientific men to contribute papers should have power to make the final selection of reporters.

SUB-COMMITTEE FOR THE SELECTION OF REPORTERS.

A meeting was held after the business of the Organising Committee was completed.

Nominations with reference to reporters recommended by Committees in the various countries and colonies were considered. A list was drawn up, but it was considered inadvisable to publish this list until the various individuals had given their formal consent to act.

NORTH OF SCOTLAND VETERINARY MEDICAL SOCIETY.

The half yearly meeting was held in the Royal Hotel, Aberdeen, on August 30th. The President, Mr. W. J. Marsden, Banff, occupied the chair. The following gentlemen were present: Messrs. Anderson, Keith; Brown, Banchoy; Beattie, Longside; Cumming, Culter; Crabb, junr., New Aberdour; Clerk, Stonehaven; Hepburn, Aberdeen; Howie, Alford, hon. sec.; Kerr, Ellon; Murray, Cullen; Morrison, New Deer; Marshall, Aberdeen; Niven, Kintore; McVean, Craigellachie; McBryde, Stricken; Sievwright, Tarland; Skinner, Oldmeldrum; and Laing, Elgin.

Visitors: Messrs. Conner, Banchoy; and Howie, jun., Alford.

Apologies were intimated from Messrs. Peddie, Robson, Crabb, and Sinclair.

The minutes of last meeting were taken as read.

The following gentlemen were proposed as new members:

Mr. CLERK, Stonehaven, proposed by Mr. Cumming, seconded by Mr. Brown.

Mr. CONNER, Banchoy, proposed by Mr. Marshall, seconded by Mr. Hepburn.

A letter was read from Mr. Jas. Peddie, Dundee, regretting his inability to give a demonstration on Oophorectomy or Hysterectomy, at the August meeting of the Society, owing to stress of work in connection with camp, and examination duties. Mr. Peddie stated that the operation was not "off" but only postponed.

SOME INTERESTING CASES.

Mr. WM. HEPBURN, F.R.C.V.S., Aberdeen.

Mr. President and Gentlemen,—When asked by our Secretary to fill the gap occasioned by Mr. Peddie's inability to be present, I thought I would show you a few specimens, with short notes thereon, in the hope that they might prove of some interest.

I. Chondroids of the Guttural Pouch. The subject, a valuable Clydesdale gelding, had an attack of influenza during the spring of last year, and had subsequently developed a chronic nasal discharge, which had persisted in spite of every treatment adopted.

I was consulted after he had been ill for some considerable time, and on examination found him in a rather unthrifty condition, manifesting a little pain and swelling in the left parotid region, giving an occasional cough, and showing a slight muco-purulent discharge from both nostrils, more particularly from the left. From the condition of the animal, together with the history, that the case had been a protracted one, I diagnosed chronic catarrh of the guttural pouch with the

formation and retention of pus therein, and in all probability an operation would be necessary.

After a lapse of about two months, the animal was again brought to my notice. During this period he had been at grass, but was not thriving, and had shown an intermittent discharge from the left nostril. I advised further examination, and operation if necessary. The morning after his arrival at my place I made a careful examination, and was surprised to find that the swelling exhibited on my first examination had entirely gone, in fact there appeared to be little amiss with him. Owing to the absence of some definite symptom I decided to keep him under observation before adopting such drastic treatment as operation. After he had been in the loose-box for ten days I detected a slight sound during inspiration, which was more in evidence when feeding, and on giving him a drink of water a few clots of muco-purulent material came down his left nostril. I then decided to explore the pouch. I selected Viborg's triangle for the seat of the operation, which was done standing, the animal previously having a local administration of cocaine and adrenalin.

On getting into touch with the pouch wall I felt a few hard concretions, but on pressure these disappeared, and I had to use a sharp seton needle to penetrate the membrane. On introducing my finger I was astonished to find quite a mass of material lying fore and aft of the point of entrance. I enlarged the opening, and with a blunt instrument and frequent irrigations removed a quantity of chondroids weighing about 30 ounces.

The subsequent treatment consisted of daily irrigations, with antiseptics and astringents—creosol, iodine, acid carbolic, zinc sulph. I varied these dressings every other day or two, and finally used mild astringents only.

The animal made a complete recovery, was put to work two months afterwards, and was eventually sold at a high figure.

The point of most interest, to me, at least, was the inability to detect some trace of this quantity of material, particularly as repeated examinations were made in the endeavour to localise some substance in the pouch.

II. A Tuberculous Laryngeal Tumour in the Horse. The subject was a five-year-old Clydesdale mare, which had been ailing for two months prior to the date of my examination, and had been subjected to the usual treatment adopted for so-called "sore throat."

I found the mare in poor condition, manifesting considerable difficulty in breathing and swallowing, with a slight discharge from both nostrils, and a temperature of 102 F. On careful examination between the parotid glands a more or less hard substance was detected, and I formed the opinion that this was associated with the guttural pouches. The breathing was so stertorous that auscultation of the chest did not reveal anything. It was quite evident from the general condition that drastic treatment was urgently required if the mare were to have a chance at all. I advised the owner to send her in for operation, which was done, and I again operated through Viborg's triangle, but had to resort to tracheotomy soon after commencing, owing to the distressed breathing. On exploring with my finger I found I had a tumour-like formation to deal with, dovetailed in between the parotids, and adhering to the posterior walls of the guttural pouches. I enlarged the opening to allow my hand into the region, and after careful dissection removed a fleshy tumour, in size roughly half-a-pound. In excising it I opened both guttural pouches, which contained a quantity of thick mucoid fluid.

On cutting into the tumour it presented an appearance not unlike tuberculosis, but I was reluctant to believe that such was the case. I sent a portion to Prof. Gofton, who very kindly examined it microscopically, and found it to be tuberculous. Upon this I tested the mare with tuberculin, but with a negative result; the

only peculiarity being that her temperature became markedly sub-normal.

After the operation the mare began to feed, often finishing her food with apparent relish. The tucked-up appearance of the abdomen, however, still persisted, and the respiratory movement continued to be more or less increased, and in consideration of these symptoms I concluded that the affection was not a local one, as at first appeared, I therefore advised the owner to have the mare "put down."

The post-mortem examination showed the lungs extensively affected with tuberculous nodules. The small bowels were similarly affected throughout, the nodules being formed in the wall of the bowel. On opening these nodules they were found to be excellent examples of tuberculous ulcers. In addition to the tuberculous lesions, small tumours were in the mesentery, which on microscopical examination were found to be sarcoma of the spindle-celled variety.

The photos show pretty clearly the extent of the disease in the lungs and bowel. The oldest lesions were found in the bowels, from which one is inclined to infer that ingestion had been the means of infection, probably contracted while the mare had been at grass with infected cattle.

3. Tuberculous Bronchial Gland from ten weeks old Calf. The subject was a cross-bred calf, and it shows the virulence of some strains of the tubercle bacilli, and the effect of contact of the young with tuberculous cows.

History. This calf was born apparently healthy, and the dam was to all appearance in perfect health. When about a week old it was tied up in a stall beside a cow which was ultimately found to be affected with pulmonary tuberculosis. I examined the calf when it was about three weeks old, and found it exhibiting lung symptoms, with coughing. While making this examination I observed that the cow was breathing fast and giving an occasional cough, but otherwise was in good milking condition. After examining her I had no hesitation in informing the owner that she was suffering from acute tuberculosis of both lungs, and advised her immediate slaughter.

My opinion was that the calf was similarly affected, and that it would do no good. The owner was reluctant to have it slaughtered, as he thought it had got a chill, as it was observed to be ill about a week after it had been put into this stall. The animal did not improve and it was slaughtered at the ten weeks.

The post-mortem examination showed both lungs to be a mass of tuberculous nodules, and the bronchial glands very much enlarged. The calf was, no doubt, infected from the cow, which was kept for dairy purposes, and the case clearly proves the necessity for weeding out such animals, and confirms the soundness of the system now being adopted by some breeders of pure stock, of removing the calves from contact with the dams immediately after birth, and keeping them in separate houses, except during the times of suckling.

DISCUSSION.

Mr. BEATTIE thanked Mr. Hepburn for his exceedingly interesting cases. He had a case of what he took to be guttural pouch disease in hand just now. There was enlargement of the region of the throat. He had opened up the guttural pouches, but only got a thin fluid. He then opened the parotid gland and got away a quantity of thick mucoid fluid. The case was still under treatment, but he regarded it as a case of parotid fistula.

Mr. MARSHALL congratulated Mr. Hepburn on the success of case No. 1, and said the chief difficulty appeared to be diagnosis. It was remarkable that such a large quantity of chondroids should have existed in the pouches without giving evidence of their presence

by swelling. They were very interesting cases, and would be a guide for the future.

Mr. McVEAN thought the cases were unique, and presented great obstacles to successful diagnosis.

Mr. SKINNER said they were all indebted to Mr. Hepburn for recording these interesting cases. The method of operating struck him as being very simple, as the text books gave very elaborate directions for performing the operation in the different ways. He himself had never opened the pouches except once, and that accidentally, in the course of lancing a strangles abscess.

Mr. SIEVWRIGHT referred to the case of tubercle in the calf, and thought there was no doubt that the calf had been infected by the cow standing in same stall.

Mr. ANDERSON said the cases were extremely interesting. So far guttural pouches had been very kind to him, as he had up to now had nothing to do with them.

Mr. MORRISON had had no personal experience of chondroids, but had operated for pus in the pouches. He mostly used his finger for forcing his way into the pouch after incising the skin. He would like to ask Mr. Hepburn if in Case 2 there was diarrhoea, as it was usual to get that in cases of tuberculosis of the bowels.

Mr. BROWN, in thanking Mr. Hepburn for his interesting cases, thought the tubercle in calf was about as early as one could get it. He had had no cases of guttural pouch disease to deal with, but thought a good way of operating would be to incise the skin with a scalpel and then use a blunt pair of scissors closed; push them in direction of pouch by way of a probe: then open the scissors and withdraw. This would serve to enlarge the opening without danger of causing hæmorrhage.

The PRESIDENT asked the members to accord to Mr. Hepburn a hearty vote of thanks for bringing forward three such interesting and instructive cases and the trouble he must have put himself to in preserving the specimens and getting the photographs done. He was sure that such cases well recorded would be a great help to them when they met with similar ones.

Mr. HEPBURN, in thanking the members for their appreciation of his paper, said that he would not have been able to diagnose Case 1 unless he had seen it in the spring. In reply to Mr. Morrison, there was no diarrhoea in Case 2, but there was marked polyuria.

FEES PAID BY COUNTY COUNCILS.

The SECRETARY informed the meeting that he had been in correspondence with the County Clerk for Aberdeenshire, and had sent him a copy of the scale of fees drawn up by the Council of the National Veterinary Association, and also the booklet showing the position occupied by the various counties in Britain. He was very pleased to inform them that he had received the following letter from the County Clerk:

Aberdeen, July 10th, 1913.

Dear Sir,—I have now to state that I informed the Local Authority at a recent meeting that you had made suggestions that the scale of fees payable to veterinary inspectors in the county should be revised, in view of the scale of fees recommended by the Council of the National Veterinary Association, a copy of which you sent to me.

The Local Authority have remitted to sub-committee with powers to confer with representatives of your Local Branch of the Veterinary Association and to submit a revised scale of fees. I would suggest, therefore, that a meeting of the local branch of the Association should be held for the purpose of considering the scale recommended by the Council of the Association, and that one or two representatives of the branch Association

should be appointed to confer with my sub-committee regarding the revision of the existing scale.

Yours faithfully,

(Signed) WILLIAM MURISON.

The SECRETARY stated that he had replied to Mr. Murison's letter and asked him if the statutory meeting in August would be in time for his sub-committee, and had received an answer in the affirmative.

The PRESIDENT said it was very satisfactory that the Aberdeenshire men had such an accommodating County Clerk, and hoped that the inspectors in the neighbouring counties would receive the same courtesy from their county officials.

The meeting discussed the "National" scale of fees. It was agreed that the fees suggested by the "National" were much in advance of those paid in the north of Scotland, and it was ultimately resolved to draw up a scale of fees which might reasonably be accepted by the various county councils. After a long and careful discussion, the following list was drawn up and the Secretary was instructed to have it printed and distributed amongst the members.

NATIONAL VETERINARY ASSOCIATION.

(NORTH OF SCOTLAND DIVISION).

Fees and Allowances payable to Veterinary Inspectors agreed upon at a meeting held on August 30th, 1913.

ANTHRAX:—

For visit and inspection of single animal	7/6
Microscopic Examination	5/0
Inspection of contact animals up to 20	5/0
Every additional 10 or part thereof	1/0

ATTENDANCES AND SUBSEQUENT VISITS:—

For each ordinary visit	7/6
For an attendance rendered necessary by any circumstance which the Committee or Sub-Committee may, upon the Report of the Inspector, consider sufficient, a sum not exceeding	21/0
For an attendance at a meeting of Sub-Committee	10/6

MARKETS, PUBLIC SALES, MARTS, ETC.:—

Half-day, <i>i.e.</i> , not exceeding four hours	21/0
For each additional hour	5/0

CERTIFICATES:—

For every set of Certificates, Licences, Reports, etc. given pursuant to an order of the Board of Agriculture, or of the County Council—excepting Tuberculosis	2/6
For each set under Tuberculosis Order of 1913	7/6

GLANDERS OR FARCY, AND TUBERCULOSIS:

For applying the Mallein or Tuberculin Test for any number in any holding or stable—with mileage for two visits extra	21/0
Mallein and Tuberculin per dose	1/0
For attendance to value horses or cattle	7/6
Valuing cattle under Tuberculosis Order, 1913	No fee.
Post-mortem exams. duly authorised (and mileage)	10/6
Microscopical examinations for Tuberculosis	10/6

MANGE IN HORSES:—

Inspection of single horse	7/6
Inspection of contact animals	5/0
Microscopical examination	5/0

SHEEP SCAB:—

For visits made for inspection and examination of sheep and also for re-examination—Flocks of 250 and under	21/0
For each additional 50 or part thereof	5/0
Microscopical examination where necessary	5/0

MICROSCOPICAL EXAMINATIONS:—

In any disease not otherwise provided for	5/0
---	-----

TRAVELLING ALLOWANCES:—

For travelling by Railway, 3rd Class fare
 For cab hire (when necessary) from a railway station, per mile, one way 1/6
 For travelling otherwise than by railway, per mile, one way 1/0

TELEGRAMS AND POSTAGES:—

The cost of necessary telegrams and postages to be allowed.

(Signed) WILLIAM MARSDEN, President.
 GEORGE HOWIE, Hon. Secretary.

The following gentlemen were appointed as representatives to wait on the various County Councils:

For Aberdeenshire:—Messrs. Marshall and Hepburn, Aberdeen; and Howie, Alford.

For Banffshire:—Messrs. Anderson, Keith; and Marsden, Banff.

For Kincardineshire:—Messrs. Clerk, Stonehaven; Robson, Laurencekirk; and Cumming, Culter.

For Morayshire:—Messrs. Laing, Elgin; and Rutherford, Forres.

It was further agreed that the neighbouring counties should await the result of the negotiations of the Society with the Aberdeen County Council before taking any steps with the neighbouring Councils.

DEMONSTRATION LECTURES.

The SECRETARY stated that during the interval since last meeting he had been in communication with Mr. Wm. Brown, M.R.C.V.S., the newly appointed lecturer on Veterinary Hygiene to the Aberdeen Agricultural College. He would like to say that Mr. Brown had entered into the matter with his usual keenness, and that he had received permission from the Board of Agriculture for Scotland and the Governors of the North of Scotland College of Agriculture to give four demonstration lectures in the laboratory of the College to the members of the Society.

Mr. BROWN said he thought three demonstrations should be sufficient. He would like all those who had good microscopes to bring them along, and if anyone had a case of tuberculous udder, to bring specimens.

ELECTION OF OFFICERS.

President.—Mr. Wm. Marshall, Aberdeen.

Senior Vice-President.—Mr. D. Cumming, Culter.

Junior Vice-President.—Mr. William Hepburn, Aberdeen.

Hon. Sec. and Treasurer.—Mr. G. Howie, Alford.

Council of Management.—Messrs. Anderson, Crabb, McPherson, Brown, Sievwright, Murray (Cullen), and Kerr.

The meeting terminated with a vote of thanks to the President, which was heartily responded to.

GEORGE HOWIE, Hon. Sec.

CENTRAL VETERINARY ASSOCIATION OF IRELAND.

The annual meeting was held at O'Carrell's Hotel, Ballinasloe, on the 6th October. Mr. B. P. J. Mahony, President, occupied the chair, and other members attending were Messrs. Doran, Moffett, Howard, Clancy, Treacy, Dawson, Bolton, O'Dea, Nolans, Miss Cust (visitor), and E. C. Winter, Hon. Sec.

Letters regretting inability to attend were read from Messrs. Heney, Healy, and McKenny.

The SECRETARY asked if the Treasurer were to remit the promised subscription (second instalment) to the National meeting, and this was ordered to be done.

Members in Arrear.—The SECRETARY submitted a

list of defaulting subscribers, which he said were hopelessly in arrear. He repeatedly sent them circulars, but had absolutely no replies. He asked, Are we to wipe them off the list?

The CHAIRMAN: Did you give them notice that these subscriptions should be paid?

The HON. SEC.: Yes, and sent them circulars as well as private letters. There are a lot of them three and four years in arrear, and I don't see why they should be left on the list. Their names should be struck off. Each member said he would see six or seven of those gentlemen on the arrears list, but it did absolutely no good. I don't think this at all fair to the members of the Association who do all the work.

Mr. DAWSON: Are they not people that you could see occasionally, and get some money from them?

The CHAIRMAN: One of you gentlemen ought to write a resolution and send it in, that they get a last notice, that if they do not pay their names will be struck off the list.

Mr. BOLTON proposed that any member not having paid his subscription for three years, be struck off the roll.

Mr. CLANCY seconded, and it was unanimously carried. It was also decided that this resolution be embodied in a circular making a final request for payment.

NOTES ON CASES.

(I) Mr. TREACY brought before the notice of the meeting, a dog suffering from "jumps." The dog was two years old, and had suffered in this way since she was six months. The owner told him the animal used to get fits and fall. She was given some bromides, and he (Mr. Treacy) believed some arsenic. She works perfectly, and never shows signs of the "jumps" when retrieving.

Mr. WINTER: How long does the owner say this exists?

Mr. TREACY: Since the animal was six months old.

Mr. DAWSON: My impression is, that if you can get them in the early stages, you can do something with them, but not when they get on in years.

Mr. MOFFETT: Had she any distemper?

Mr. WINTER: She must have had suppressed distemper. Degeneration of the nerves is the probable cause.

Mr. TREACY: The owner told me the dog had no distemper; it must have been slight, and he did not notice it. I don't think treatment would have been any good for this case.

(II.) Mr. DAWSON said this reminded him of a case he had with a horse that had been cast as a "shiverer." The owner brought him, and he (Mr. Dawson) did not consider him a "shiverer." He wanted the opinions of some of the gentlemen present as to the case. When you stood in front of the horse he was all right, and when you stood behind him, he was a "shiverer." When you take his head and ask him to back, he shows all the signs of tetanus.

Mr. WINTER: How long does tetanus last?

Mr. DAWSON: I know a horse that was castrated and got it, and never got better. He did carting work for fifteen years.

Mr. WINTER: The longest time I ever saw it last for, was three months.

Mr. DAWSON said what he used was 3oz. Mag. sulph. solution hypodermically in the neck, and in most cases the animal got better.

Mr. TREACY said he used bromide of potash in several cases, and the Chairman said he found chloral hydrate very successful.

Mr. WINTER: In my last three cases I gave them nothing but calomel, with the best results.

Mr. BOLTON: I have had several successful cases with serum.

Mr. DORAN: Two or three cases recovered with me in the last month, and I treated them with mag. sulph. and calomel.

(III.) Mr. DAWSON related another case he had. A horse was brought to him, and its jaws were locked, and locked for 48 hours, and the rest of his body was semi-paralysed.

(IV.) Mr. WINTER said he had a funny case last winter. There was a horse suffering from tetanus for six or seven weeks, and got better. Some three or four weeks after he was out in a field and got paralysed, and was shot. He (Mr. Winter) saw him and could not say what was wrong. Was it a recurrence of the tetanus? He believed himself it was a blood clot.

The CHAIRMAN: It was probably a clot.

SEVERAL ODD CASES.

By Miss ALEEN CUST.

Miss Cust, who was received with applause, said she knew it was usual to make excuses for a paper, even when it was not necessary at all, but it was in her case. Her paper was very indifferent as she had not time to prepare it, so she craved their kind indulgence. The paper contained a number of cases met with by Miss Cust in the course of her professional work.

(I.) Do any of you ever twist a glicking cow's tail round her hind leg from the inside, and get somebody to catch hold of it and pull the leg back each time she tries to kick you? Because I always try this, and thought it infallible and harmless, and efficacious, until one day, somehow, I can't say how, the cow gave a sort of lurch, the man "held his hoults," and lo, the tail came off, skinned as neatly as a foxen brush, leaving about twelve inches of bone exposed. The man fell down amidst a general roar of delight. A sense of humour is invaluable at such times!

(II.) I was called to see a cow which had calved ten days previously, but had, as the owner described it, only partly cleaned. The decomposed state of the placenta may be imagined. There was about eighteen inches of it hanging down, the cow not feeding, no milk, and not a promising looking subject. I had cuts on my hands, and to tell you the truth, I was not keen on making a manual exploration. Luckily, however, I did so, and found a strong membrane passing from wall to wall of the vagina. The band was about two inches deep, and three-quarters of an inch thick. Round this, as if hanging on a line, was the rotten placenta, which I cut through, to the immediate relief of the cow, which at once began to eat, and soon was well again.

(III.) A mare was brought into my yard with a history of having the previous night got into a field of half ripe oats, before which she was in perfectly normal health. The symptoms shown were most remarkable. The hind legs at each step being so sharply flexed that they actually hit the mare's belly when she walked. I gave a physic ball, and in two days she was all right again.

(IV.) The other day, when examining the liver of a cow which had died calving, I found the bile ducts full of chewed grass. The gall bladder was full of gall stones and the liver was full of flukes. How did the food get into the bile ducts?

(V.) A pony mare with a history of not being in foal that year, and of having fallen in harness some weeks previously, was brought to me, as her owner feared she "would bleed to death." Occasionally a big clot of blood would fall from the vulva, and on examination, first manually, then with a speculum, I was able to satisfy myself that the hæmorrhage came from the uterus. There was no lesion at all in the vagina, which appeared perfectly normal. The interesting part is—not in my treatment, which was astringent irrigations, and Ext. Ergot internally—but what was the cause? The pony

recovered in about three weeks and is still in perfect health, and this happened over a year ago.

(VI.) A cow brought with a fistula in the left flank low down, from which the contents of the bowel—not the rumen, were exuding. History said "she had a lump there for two months which burst seven days ago." The noteworthy fact was that she seemed in perfect health in every way, and was chewing the cud, milking, and doing everything a healthy cow would do, and was not one bit put about by the fistula. I advised "Do nothing"; and the cow still lives, though that was 18 months ago.

(VII.) A kid got its gastrocnemius tendon caught in the coupling hook with which it was chained to its dam. Antiseptic treatment was applied within a few hours of the accident, and no more was thought about it. A fortnight after, my attention was drawn to a curious distressed note in its bleat, and it was then seen that the kid had tetanus. Anti-tetanus was used, but it died speedily, and most typically.

Miss CUST related another case which she had recorded. A horse while negotiating a broken gate got an injury in his side, just where the lung is tapped. You could put two fingers into the wound, and a small piece of something came out of it. What came through the opening? Was it a piece of the lung?

Mr. WINTER: If it were any other situation you would say it was a piece of the bowel.

Mr. DAWSON: It was the corner of the lung.

Mr. WINTER: It could not be anything else.

Mr. HOWARD said he had a case of a horse with an enlargement on its side; when the horse was exercised it increased, and when the animal was at rest it decreased.

Miss CUST told of a case where a young mare got a fall and after six weeks it used to pass great clots of blood. This had continued for three weeks, and she was confident that the animal would bleed to death. She gave Adrenalin, and the animal fortunately recovered.

Mr. DAWSON told of a case where he had to plug the vagina. The plug was left in for three days, then his assistant took it out, and the animal lived no time. The plug was taken out too soon. The plugging was going to save the animal's life, but he considered three days sufficient to leave it in.

The CHAIRMAN said he very frequently plugged animals without any harm. He left it in in some cases, and let it come out itself.

Miss CUST said she believed, in the case related by her, that it came from the uterus.

Mr. DAWSON: Was there any chance that it was coming from the kidneys?

Miss CUST: No.

Some of the members said it might be a kind of hæmatoma.

Mr. DAWSON: What diagnosis do you get off that? Is it clots of blood?

Miss CUST: Yes.

Mr. TREACY: Quite a number of them are on my list from this.

Mr. DAWSON: My line of treatment in this case is Perchloride of iron. I give 2 oz. three times a day.

Miss CUST: That is my treatment.

ETHICS.

Miss CUST said she would like the opinion of the meeting, as to how members should act in the case of some hypothetical cases which were going to be put before them.

My first case was: "B" was not long started in a district and was treating a certain case. "A" is called to the case and knew nothing about "B" treating it, but the owner of the animal does not want "B" any more. What is "A" to do?

Mr. WINTER: There is nothing for him to do except continue to treat the case.

Mr. TREACY: The only thing is that the owner should let "B" know definitely that he had finished with him.

The CHAIRMAN: I think "B" should give up the case to "A." A similar case occurred to me. The animal was brought to me and I saw it. "B" wrote to me and told me he had this case in hand, and was I going to take it from him. I wrote then to the owner, who replied that "B" had the case six months previously and gave it up. I sent the owner's letter to "B" and he said he had seen the animal later, and claimed the case. The result was, that a third man was called in and neither of us got it.

Miss CUST: Then the meeting decides that "A" is to go on.

Mr. HOWARD: "B" should be informed.

Proposition II. Miss CUST: "A" is called and is told "B's" opinion is that the case is hopeless. "A" hesitates to go, but is assured "B" will not be employed again. "B," however, pays another visit; he is entitled to a further fee?

Mr. WINTER: That depends on the client.

Mr. O'DEA: It puts "B" in a wrong place.

Miss CUST: "A" is to go on again.

Mr. DORAN said with regard to the question of fees, in his district they hardly ever get a second fee.

The CHAIRMAN: And you go twice for one fee.

Mr. DORAN: As a rule they never send for you a second time. When they call you in first they expect you will see the case through.

Mr. HOWARD drew attention to a practice in the South and West of Ireland, where veterinary surgeons examined horses for insurance companies for fees of 3/-, 4/-, and 5/-. A case came to his knowledge where one of the gentlemen present was asked to examine a horse valued for £500 by an insurance company, and was offered a fee of 5/-. He refused it, and another man, four miles away, examined the horse for 5/-.

Mr. CLANCY said the case was his, and it was a young man did the work.

Miss CUST: The veterinary surgeon should be paid on the value of the animal.

Mr. NOLANS said he had a case and refused to work at the figure offered, and subsequently certified for £1 1s. fee on behalf of the client.

Mr. CLANCY: I think we should deal with the people that do this—the insurance companies.

Mr. WINTER: I had three applications to examine horses, and the insurance company said that they only got £2 and they have to pay agents, and consequently have very little out of it. I told them to let the owner get a certificate, and he did, and I got my fee.

The CHAIRMAN: The only thing is to bring pressure on the individual.

Proposition III.—Miss CUST: A position becomes vacant in "A's" district, without consulting him. "B" sends in his application, although "A" did not offer himself for a vacancy in "B's" district. Is "B" playing the game?

Mr. WINTER: No.

Mr. HOWARD: It is not professional honour.

Miss CUST: "B" is not playing the game.

Proposition IV.—Miss CUST: "A" is for years working for a man, and for no reason the owner employs "B." "B" is away "at play" when required, so "A" is called again. Should he go?

Mr. NOLANS: Yes, and hand over the case on "B's" return.

Mr. WINTER: He should tell his client to go to a very warm place, that I will not mention.

Mr. DAWSON: Certainly, let "A" go.

Miss CUST: "A" is to go.

Proposition V.—Miss CUST: "A" is required to make a post-mortem. He finds when there that there is

a man on the other side. Should he wait for him, and how long?

If too long, perform the post-mortem, disturbing the carcass as little as possible.

Proposition VI.—Miss CUST asked, in case of running over a dog with a motor car, should you stop and attend, or go on?

The best thing to do, the meeting decided, was to go on.

The CHAIRMAN: You have all heard Miss Cust's paper, a very interesting one too, which was evident from the lively manner in which the discussion was kept up. They were all very thankful to her for the nice paper.

Mr. WINTER said Miss Cust's paper was not laboured, it was the sort of paper he was always trying to get; such notes always provided lively, although informal, discussion. The discussion on such a paper was beneficial to all, and there was nothing so boring as to sit down and listen to a long paper, most of which had been copied from some authority. He found it very difficult to get members to supply papers, although it only took a short time, and sometimes meetings fell through, owing to broken promises. They, country practitioners, had not time to write a treatise, but something short would do. There was no meeting, he believed, that he ever attended but he learned something. He begged to propose a hearty vote of thanks to Miss Cust for having filled the breach.

Mr. BOLTON seconded the vote of thanks, and Miss Cust replied expressing her thanks for the manner in which her paper was received.

Mr. HOWARD: I do hope before long that the Central Veterinary Association will see Miss Cust an M.R.C.V.S., as I think she would be an ornament and a shining light in the profession.

Mr. NOLANS kindly consented to read a paper at the meeting to be held in Dublin in January.

This concluded the business, and Mr. Howard proposed a vote of thanks to the Chairman. He came there that night, a very long distance, to preside over that meeting, which showed how deep at heart he had the interests of the profession. He hoped they would have him at many more meetings.

Mr. WINTER, seconding, said a hearty vote of thanks was due to Mr. Mahony for having come such a distance there that night to preside.

The CHAIRMAN said he was very thankful for the vote of thanks. It was a pleasure for him to come when he heard Miss Cust was to read a paper, and he knew he would be well repaid for his time and the distance travelled. He could go back well pleased and proud that he had attended the meeting.

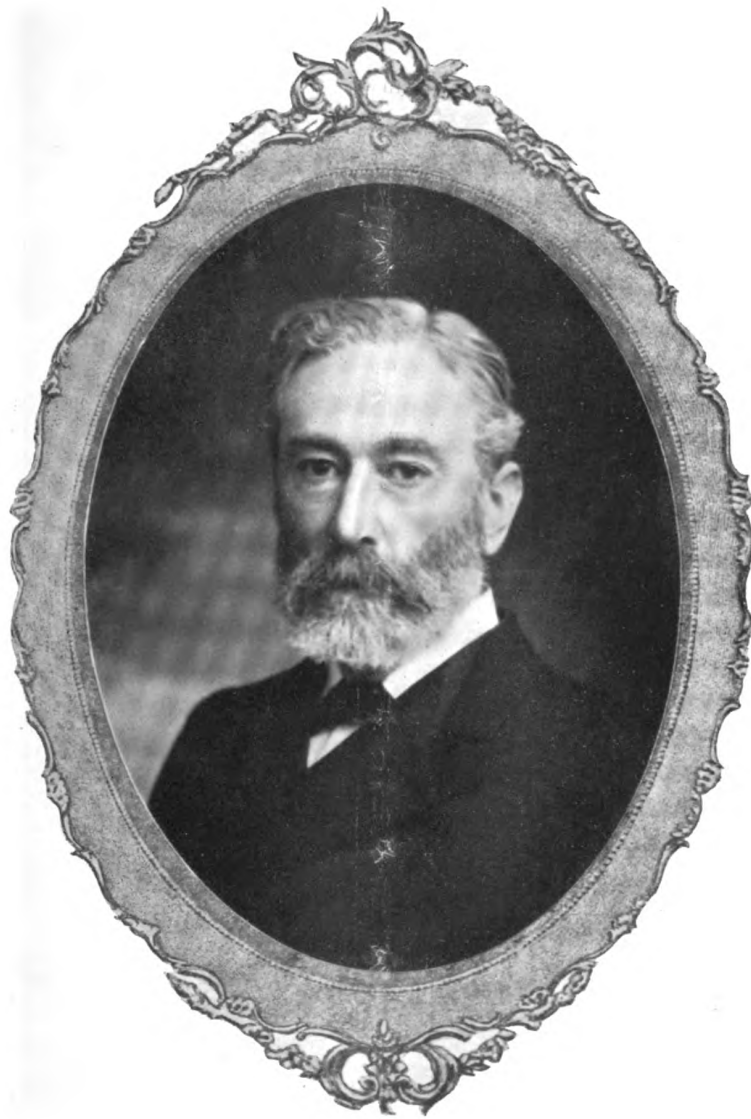

E. C. WINTER, Hon. Sec.

Alleged Breach of Warranty.

At the Carlisle County Court on Tuesday, October 14th, before His Honour Judge Gawan Taylor, Robert Verers, farmer, Belle Vue, Carlisle, sued William Cowle, Woodhall Hill, Haydon Bridge, for the return of £23 paid in respect of a contract alleged to have failed. The plaintiff claimed the return of the purchase money for a cow which he purchased at Harrison's Auction Mart, Carlisle, on April 26th, 1913, for £23, under the conditions of sale at the mart. As an alternative the plaintiff claimed damages for breach of the warranty.

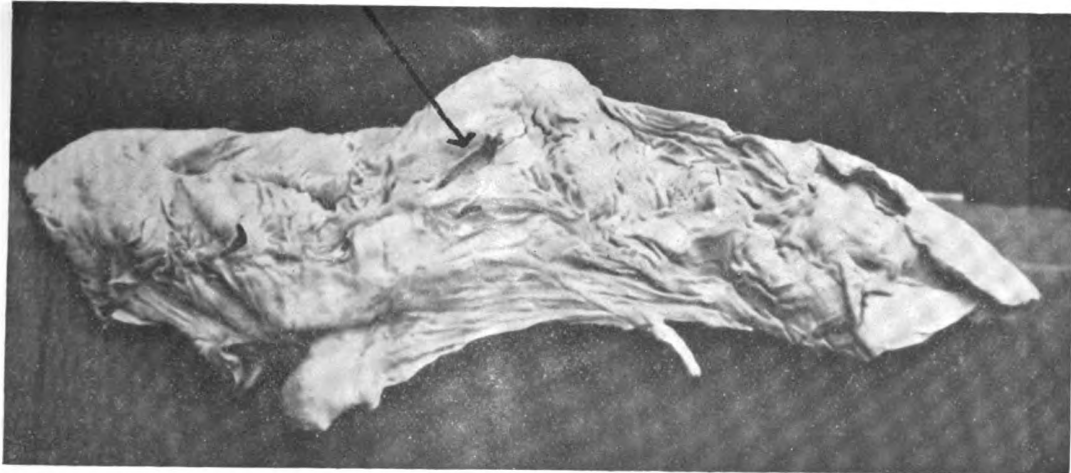

Mr. G. A. Lightfoot appeared for the plaintiff, and Mr. Gibson, Hexham, was for the defendant.

Mr. Lightfoot said they contended that from the conditions of the mart they were entitled to repudiate the bargain. It was true there was no implied warranty in regard to tuberculosis, but this cow, apart from the tuberculosis, was found to be suffering from induration

(North of Scotland V.M.A.)

CHONDROIDS FROM GUTTURAL POUCH.

of the udder, which was an unsoundness and an unhealthy condition within the meaning of clause 2 of the conditions of sale. It might be suggested that induration of the udder was the same as tuberculosis, and whilst the induration of the udder might come from tuberculosis it was by no means bound to result in tuberculosis.

Robert Vevers, the plaintiff, stated that on Saturday, April 26th, he visited Messrs. Harrison's Auction Mart, Carlisle, for the purpose of buying a newly-calved cow for use in his milk business. A roan cow, belonging to Mr. Cowle was put into the ring, and witness said to defendant, "If I buy this cow it will have to pass the veterinary test." Mr. Cowle said "It will pass anything." Witness had had trouble with the cow the previous week, and that was the reason why he spoke to Mr. Cowle. The cow was knocked down to witness for £23, and before it left the mart he and his wife saw it milked. Mr. Cowle was there when the cow was milked. The cow was taken out on the Saturday, and on the Monday Mr. Craig Robinson examined the udder, and pointed out its condition.

In answer to his Honour, witness said that it was the duty of Mr. Robinson to examine cows.

Continuing, witness said that Mr. Robinson pointed out to him that there was a hard part in the udder, which witness felt. Witness did not know what was wrong, and Mr. Robinson, on that day, put the animal to a test. He also came to witness's place on the Tuesday and tested the cow again. In consequence of this the cow was sent back to the auction mart on the Saturday. The veterinary surgeon instructed the auction mart officials not to sell the cow but return it to the vendor.

Cross-examined: From what Mr. Cowle said witness thought that he would take the cow back if it would not pass the test. When a man named Bowman at the auction mart said that the cow would be taken back if it did not pass the test, he did not hear Mr. Cowle say anything in the byre, but he may have spoken to witness's wife.

Margaret Vevers, wife of the last witness, deposed that she was outside the ring in the mart when this particular cow was brought in for sale. Witness's husband spoke to Mr. Cowle, after which he bought the cow for £23. She was present when the cow was being milked at the byre at the mart, and Mr. Bowman, an official at the mart, said: "Well, Maggie, have you made that one right?" She replied, "Yes, we bought it from this gentleman, and he is going to take it back if it does not pass the test." Mr. Cowle was present at the time, but witness had had no conversation with him before the sale. She answered Mr. Bowman in consequence of something her husband had told her.

Cross-examined: She did not hear Mr. Cowle say anything in the byre at the mart, and she did not think that the cow was dear. The lump in the udder might be the size of a small hen's egg.

Mr. R. Craig Robinson, official veterinary surgeon for the City of Carlisle, stated that in fifteen years he had examined between fifty and fifty-five thousand cows' udders. He spoke to examining this particular cow, which he found had an indurated udder in a chronic state. The consequence was that the animal would not give as much milk in that quarter, and it might progress to such an extent that the quarter would be lost altogether. It would prejudice the cow, and would make it less useful.

By His Honour: Tuberculosis was the most uncommon cause of induration of the udder. The commonest cause was previous inflammation, resulting in a chronic change taking place in the tissue. The induration had evidently been present for three or four months.

Continuing, witness said he injected tuberculin, and

at that time the temperature was 101.2, at the ninth hour afterwards the temperature was 104.4, and at the twelfth hour 106.4. He came to the conclusion that the cow was affected with tuberculosis as well as having an indurated udder.

By his Honour: The tuberculin test was recommended by the Board of Agriculture, and was the most up-to-date method used for the purpose of detecting tuberculosis. If this animal had not been affected the temperature would have remained stationary. The induration of the udder was a notifiable disease, and people would hardly buy a cow so affected.

Cross-examined: An indurated udder might contract and shrivel, but would not dissolve altogether. This was the first cow in fifteen years that litigation had arisen from.

Mr. Lightfoot: It is rather a rough time for the lawyers. (Laughter).

After a long legal argument, Mr. Gibson called evidence for the defence.

Francis Pickering, Hexham, assistant veterinary inspector for the Northumberland County Council, stated that he examined the cow on May 6th. In his opinion the udder, though thickened in the near hind quarter, was not indurated or tubercular. He handled the udder very carefully, and found that there was a congestion of the blood vessel. In his opinion the cow had not an indurated udder.

Cross-examined: There was a small disparity in the udder, but this was nothing out of the common. From what Mr. Robinson said regarding his diagnosis of the udder on the 26th of April, and what witness saw on 6th of May, he should say that Mr. Robinson was mistaken.

Charles Carruthers, veterinary surgeon, Haltwhistle, stated that he examined the cow on June 1st and 2nd, when he found nothing wrong with the udder. There was nothing abnormal, and nothing with which he could connect disease. The animal was sound and healthy.

By Mr. Lightfoot: He supposed that he and Mr. Robinson had examined the same cow, but he did not know. (Laughter). He did not understand how Mr. Robinson had come to his decision regarding the indurated udder. He thought Mr. Robson must have found a blasted udder.

By his Honour: If the cow had been suffering from a blasted udder it could be sold about ten days later, unless it caught cold.

Answering Mr. Gibson, witness said that farmers would buy these cows with blasted udders, and think nothing about it.

Thomas Hunter, veterinary surgeon, Newcastle-on-Tyne, said he examined the udder of the cow on October 12th, and found it to be perfectly sound and healthy.

Cross-examined: He would not swear that when examined on April 26th the udder was indurated.

His Honour in giving judgement said that he found that there was either induration or some dangerous condition less than induration, and that the cow was unsound, therefore there had been a breach of condition. There must be judgment for the plaintiff.—*The Carlisle Journal*.

The Royal Sanitary Institute.

CONGRESS, 1914.

The Council of The Royal Sanitary Institute have accepted an invitation from the Mayor and Corporation of Blackpool to hold the next Congress and Exhibition of the Institute in Blackpool, from July 6th to 11th, 1914.

* As Diseased or Exposed to Infection

The Milk Supply in Ireland.

The final and unanimous report of the Irish Milk Commission, which was appointed by the Lord Lieutenant, has been issued. The terms of reference included inquiry into the alleged scarcity of milk in Ireland, the causes, the effects on the public health, and the remedies; also inquiry into the dangers of contamination and infection of the present milk supply and the best means for guarding against those dangers. The Commissioners held 56 meetings in various parts of Ireland. They also sat in Manchester and Birmingham to ascertain the measures which are taken against contamination and infection in the large English cities. The report is divided into two parts—"The Milk Supply" and "The Purity of the Milk Supply."

The second part of the report deals with the elimination of tuberculosis among cattle and the prevention of the use of milk infected with disease. The Commission favours the modernisation of the law regarding disease in cattle. Large powers should be given to public health authorities for the regulation of dairies and the sale of milk from them, and the Dairies, Cowsheds, and Milkshops Order of 1908 should be amended. The Commissioners also recommended the strengthening of the Food and Drugs Acts in respect of the sale, storage, and adulteration of milk. A final recommendation is the appointment of a co-ordinating committee, composed of representatives of the Local Government Board and the Department of Agriculture, to deal with all matters of public health and the health of cattle in which the two Departments are concerned.

Glass Windows for Pigs.

The Rural Council at Baltinglass, County Wicklow, is sharply divided on the question: Should pigs have glass windows?

The pigs of the district, it seems, have been suffering in health from too severe seclusion. Mr. J. J. O'Ramsey, the sanitary inspector, told the Council that several had died from the "closeness" of their sties, and added that "probably the darkness produces anæmia." He recommended gates and windows for the sties at £1 10s. each. A majority of the Councillors were unsympathetic.—*Daily Mail*.

Petrol as an Antiseptic.

The following description of an operation may serve to introduce yet another use for this volatile hydrocarbon. The operation was for a large fatty tumour of the right labium major in a woman of fifty.

I took the instruments from the drawer and, instead of boiling them, soaked them well in petrol. At the house the only preparation previous to our arrival consisted of the shaving. I then bathed the site of operation with petrol, and after the incision, extraction, and sewing were completed I bathed the part once again and applied dry wool. Notwithstanding the daily soiling, by the application of petrol after each micturition the wound healed by first intention. With a wound situated in such an awkward part it is impossible to keep on an orthodox dressing, and the ease of application by an unprofessional attendant made the petrol a most valuable dressing.

At my suggestion, in several of the metal works of this district small wounds are now treated at once by spraying petrol on them, and with splendid results. My idea is to render the half-destroyed cells non-poisonous by interfering with their surface tension. These small metallic burns are very difficult to heal on account not only of the dirt, but also of the enzymes which are set free from the half-burnt cells. The enzyme products poison the wound and prevent the surface of the wound taking on a healthy appearance. By means of petrol the surface tension of the enzymes is so affected as to render them quite inert, and as a consequence the wound is allowed to remain clean and unpoisoned.

The non-irritating quality of petrol gives it a ready advantage over all the other antiseptics, especially those of the coal-tar group. Its one great disadvantage is that it is so inflammable; and unless operations or applications can be made away from a fire its use is contra-indicated.—*The Hospital*.

Dick Veterinary College Extension.

In order to provide a site for the new Royal (Dick) Veterinary College at Summerhall Square, Edinburgh, the old Summerhall Brewery had to be demolished. The work of pulling down the old buildings has been proceeding for some time, and about half of the ground has been cleared. The foundation tracks have been cut, and it is expected that part of the foundations of the new buildings will be laid next week.

On the north side of the site further demolition work was impeded by the brewery chimney, but to-day that structure about 65 feet high, and believed to be about 200 years old, was felled. Part of the brickwork had been carefully cut away, and wooden supports put in. A fire was lighted under the supports, and when these were burned through, the mass of brickwork fell with a crash, sending up volumes of dust. Prin. Bradley, of the Dick College, was among a number of interested spectators who saw the chimney fall.—*Edinburgh Evening Dispatch*.

Hunting Memorial Fund.

It has been proposed by several friends, both professional and otherwise, of the late Mr. William Hunting, that a fund should be raised with the object of erecting a memorial stone, and, if possible, instituting some prize or lectureship in memory of the deceased gentleman. A committee will be formed later on. In the meantime subscriptions may be sent to myself, who will acknowledge them personally, and through *The Veterinary Record*.

GRANVILLE GRAY.
23 Upper Phillimore Place,
Kensington, w.

October 30th, 1913.

Notices were circulated in Warwickshire to the effect that the annual audit for the collection of the Earl of Dalkeith's "wroth silver" would be held at Knightlow Hill, Ryton-on-Dunsmore, "before sunrise" on Nov. 11th, and that all those from whom payment is due are requested to attend. The ancient ceremony is quaint. People assemble around a large block of stone, in the centre of which is a receptacle, and the Earl's steward having read "The Charter of Assembly," the representatives of the different parishes, nearly thirty in number, are called upon to drop their contributions into the hole in the stone. The individual amounts vary from 1d. to 2s. 3d., and when the custom had its inception these sums would represent an altogether different value. According to popular belief "wroth silver" was originally a payment for the privilege of using certain roads belonging to the lord of the manor.

Anti-Formin and Acid-Fast Bacilli.

A Correspondent, who desires to remain anonymous, writes us that the remark in last week's issue concerning the disintegration of acid-fast bacilli is not wholly correct, and that notably John's bacillus, besides others, is not so affected by the reagent. Does this mean that there is a difference in the technique employed?

Personal.

BROAD.—At Marlborough, the wife of Wm. T. D. Broad, M.R.C.V.S., of a son.

MR. GEO. E. KING writes:—"I desire to express my gratitude to the many friends who wrote expressing their sympathy with me in the bad accident I had in August, when a horse fell upon me, causing a compound fracture of the right leg with the complication of a punctured vein. I am pleased so say that although still very lame I am sufficiently recovered to resume my work."

"I was very very grieved to see the announcement of poor Hunting's death. My lameness prevented me paying the last tribute of respect to him. I cannot say I was surprised, for I noticed a great change in him when I saw him last in July."

OBITUARY

WILLIAM HUNTING, F.R.C.V.S., Chelsea, S.W.

Graduated, New, Edin: (Gamage), April, 1865.

The announcement last week that "no operation has been attempted" will have indicated to our readers that Mr. Hunting's condition was more than serious. The septic trouble became generalised, and his strength ebbed. He passed away peacefully shortly after noon on Friday last.

The interment was at the beautiful little cemetery at Putney Vale, on the Kingston Road, on Tuesday. The mourners were: Mr. Fred Hunting (son), Mr. Charles Hunting (brother) and his two sons; Mr. R. Brydon, Seaham Harbour, Mr. R. C. Irving, Mr. J. Emerton, Mr. Spen Kitto. There were also present:—Messrs. Nicholson Almond (Chairman, Board of Examiners, R.C.V.S.), W. H. Brown (*The Veterinary Record*), R. Bryden, Fred Bullock (Secretary R.C.V.S.), W. Roger Clarke, R. J. Foreman, Henry Gray, W. L. Harrison (Assist. Sec. N.V.A.), F. T. G. Hobday, F.R.S.E., C. J. Humphries, H. A. MacCormack (Hon. Sec. Central Veterinary Society), Dr. J. McI. McCall M.B., C.M. (Board of Agriculture), Sir J. M'Fadyean (Royal Vety. College), J. W. McIntosh, F.R.S.E., J. Malcolm (Midland Counties V.M.A.), W. J. Mulvey (Treasurer, R.C.V.S.) Parker (L.C.C.), T. Salusbury Price (Past President N.V.A.), Maj.-Gen. Pringle, C.B., D.S.O., Dir. Genl. A.V.S., W. Reekie, Vet.-Capt. Rees-Mogg (1st Life Guards), C. Roberts, F. G. Samson (Royal Counties V.M.A.), S. H. Slocock (Southern Counties V.S.), S. L. Slocock, Prof. E. S. Shave, Maj.-General F. Smith, C.B., C.M.G., Chambers Smith (Sutton), Sir Stewart Stockman (Board of Agric.), G. H. Thatcher (Solicitor, R.C.V.S.), R. C. Trigger (Midland Counties V.M.A.), E. White Wallis (Sec. Royal Sanitary Institute), Prof. G. H. Wooldridge (President Central Veterinary Society), T. Wright, and several others whose names we are unable to give.

Floral tributes, many of them very beautiful, were sent by:—"In loving memory of our dear Father," from Louie and Fred; "A sad good-bye, from Charlie and Mona," Hexham; "In loving memory," Mina; from Winifred, Percy, Mona, Lindsay, and Althea, Hexham; Mr. and Mrs. Brydon, Seaham; Sir John and Lady M'Fadyean; Sir Stewart and Lady Stockman; Henry Gray and Family; Mr. and Mrs. J. Macqueen; Mr. and Mrs. Stanley Carless; Mr. and Mrs. W. J. Mulvey; Mr.

and Mrs. Joseph Emerton; Mr. and Mrs. Leslie Brass; Capt. and Mrs. Todd Thornton; Mr. and Mrs. G. E. King; Mr. and Mrs. Spen Kitto; Mr. and Mrs. G. Urquhart; "From an Old Servant"; Mrs. Simester and Family; Mr. and Mrs. W. S. Mulvey; Mr. and Mrs. J. Willett; Mr. H. A. MacCormack; Mr. T. Wright; Messrs. Price and King; Mr. W. Perryman; Mr. E. H. Leach; Mr. W. H. Brown and Mr. J. B. Brown; President, Council, and Officers of R.C.V.S.; Principal and Staff of Royal Veterinary College, London; Principal and Staff of Royal Dick Veterinary College; Colonel Blenkinsop and Aldershot Veterinary Corps; Messrs. Almond, Bloye, and Hickes, colleagues on the Examining Board, R.C.V.S.; Directors of Messrs. J. Lyons and Co.; The National Veterinary Association; President and Fellows of The Central Veterinary Society; Veterinary Medical Association of Ireland (Harp, with motto, "Now the labourer's task is o'er"); Members of Southern Counties' Veterinary Society; The Yorkshire Veterinary Association; The South Eastern Veterinary Society; The Staff of *The Veterinary Record*; *The Veterinary Journal* and *The Veterinary News*.

The sad news reached us as the last sheets of "The Record" for the week were running off the machine; and although a few lines were inserted in *The Daily Telegraph* of Saturday, very many did not see either that, or the fuller notice of Monday morning's issue, which appeared also in *The Times*, and *The Morning Post*. Many, too, have written their regrets that they were unable to be present through illness; and others that they were prevented from other causes.

To all of these Miss Hunting desires to express her gratitude for their sympathy and kindness. So far as possible she has replied personally.

We greatly regret to record the death of Mr. Edward Warburton Nickson, M.R.C.V.S., which occurred from an attack of acute rheumatic fever at his residence at Hambleton, on Tuesday, October 14th. The deceased, who was 37 years of age, was the second son of the late Mr. Fred Nickson, and of Mrs. Nickson, of Cranford, Hornby Road, Blackpool. Educated at Rossall, Mr. Nickson studied at the Royal Veterinary College, London, and at Edinburgh University, where he took his degree. He had an extensive practice in Blackpool and the Fylde. The late Mr. Nickson took considerable interest in Freemasonry, and was to have been installed J.W. of the Fylde Lodge at the annual gathering at the Hotel Metropole. The deceased leaves a young widow, the daughter of Mr. J. W. Emmott.

CORRESPONDENCE.

REBATE ON PETROL.

Sir,

It was with great interest I read the letter from Mr. J. Holland in last week's *Record* about agitating for a rebate on petrol. We should be very grateful to him for moving in the matter, and putting it before the profession, for I am of opinion it is a great hardship to the veterinary surgeon not to be put on the same footing as the medical. As I believe most of the veterinary surgeons are now using motor cars, I think we should be up and agitating for our rights, especially now, as we are working for the public good in eradicating tuberculosis. I appeal mostly to the members of the profession in Ireland as we stand a better chance than our brothers in England and Scotland, for by the action of Mr. C. Allen, V.S., Dublin, we in Ireland do not act on juries; therefore I do not see why we should not be treated in like manner in regard to the use of petrol.

I would suggest that we should have a test case tried in the superior courts, and let those members in Ireland who have motor cars contribute to the expense. If all owners subscribe I am sure it would not be much on each. As Mr. Holland first moved in this matter, I would suggest that he should call a meeting and form a committee to take it up. I, for one, would be willing to take my share in the work.—Yours truly,

B. P. J. MAHONY.

Annetfield, Maryborough.

THE UPKEEP OF MOTOR CARS.

Sir,

As promised to several of my veterinary friends, I herewith enclose the cost of my motor for the second year, together with a copy of last year's statement which you can publish if you think of sufficient interest.

It will be noticed that owing to the greater mileage and the better result per gallon, the result works out fractionally better than last year notwithstanding the extra cost of petrol.

4-seater, 12 h.p. Delage.	1st Year.	2nd Year.
Driver's licences, insurance and other taxes	£14 8 0	£15 13 0
Tyres—repairs to same, etc.	40 7 4	50 10 1
Petrol, 445 gals.—oil and grease	32 16 0½	
" 434 gals. "		40 0 10
Other repairs	10 9 3½	8 6 8
Wages and uniform	69 14 0	71 2 0
	£167 14 8	£185 11 7

Mileage—1st year, 9,000; 2nd year, 10,500.

	1st year.	2nd year.
Miles run per gallon of petrol	20.2	24.1
Cost per mile—car only	2.7d.	2.6d.
" including chauffeur	4.4d.	4.2d.
Car, chauffeur, and depreciation at 20 per cent. per annum	5.7d.	5.4d.

—Yours faithfully,

Wigan, October 25th.

WM. WOODS.

THE PATENT MEDICINE TRADE.

Sir,

For some time past we have been, in collaboration with several veterinarians and agriculturists, enquiring into the composition of certain patent medicines, which are, as is well known, vaunted as cures for every, or nearly every, ailment. Yet in many instances the administration of such preparations has fallen under grave suspicion of causing harmful results, or even death.

We know that there is a widespread desire among members of the profession for more knowledge as to the ingredients, value and suitability of these remedies, and we have at the present moment several analyses. Before publishing these we should, however, like to extend our enquiries, and with this view, we shall be glad if our professional colleagues will send unopened bottles, or packets, of the "quack" drinks which, in their experience, are most commonly used in their districts.

Specimens may be sent either to the Chemical Laboratory, Royal Veterinary College, Camden Town, N.W., or 165, Church Street, Kensington, W.—Yours faithfully,

F. HOBDAV.

G. D. LANDER.

A STARVATION OFFER.

Sir,

As it may be of some interest to the profession to see what some County Councils are mean enough to consider a proper fee for work under the Tuberculous Order, I am enclosing you a copy of a recent Order made by the Executive Committee of the Meath County Council. Therein you will see that they offer a fee of 10s. 6d. for each case. Not each visit remember! The 10s. 6d. is to include clinical

examination of the animal, tuberculin test if necessary, microscopic examination, post-mortem, mileage, etc., etc. Everything included, except valuation and all for the large sum of 10s. 6d.

With some of the Inspectors, their district extends fifteen Irish miles from their own premises. Further comment is unnecessary.—Yours faithfully,

AN UNFORTUNATE MEATH VETERINARY INSPECTOR.

COPY OF ORDER MADE BY THE EXECUTIVE COMMITTEE UNDER THE DISEASES OF ANIMALS ACTS FOR COUNTY MEATH, AT MEETING HELD ON 27TH OCTOBER, 1913.

"That on our Clerk receiving notification under Tuberculosis Order, 1913, of any suspected case of tuberculosis under that Order he shall direct the Inspector of the district to inspect such case, and should the Inspector report to him that, in his opinion, the case is one for slaughter, he should forthwith, on behalf of this Committee, give an order to the said Inspector to value the animal, and to have the animal then slaughtered should the said Inspector deem it necessary; that a fee of 10s. 6d. be allowed to each such Inspector in respect of each such case which he is so ordered to inspect, and a further fee of 10s. 6d. should it become necessary for him to make the said valuation; this Order to be subject to the approval of the Department of Agriculture, and to hold good for six months from this date; and, provided that the Inspector accept the terms of this Order, we further consent to make it retrospective from the date the Tuberculosis Order came into force, but under no circumstances shall any mileage fees be allowed."

HUGH J. CULLEN, Secretary.

October 27th, 1913.

DIAGNOSIS.

Sir,

In your issue of the 18th inst. you kindly inserted a letter of mine in which I drew attention to articles appearing in public journals, so written that the authors arrogated to themselves the prerogative of measuring the skill and ability of others by their views and experience on various subjects.

In your issue of the 25th inst., there appears a communication of Mr. Hoare's, in which he, apparently, would like my remarks to be lightly passed over, and he misinterprets what I have written; as for instance, he states that I indicate that I do not think it desirable for a practitioner to admit the limitations of his skill, whereas what I objected to, was the publication of articles in which the writer admits his want of skill in such a manner as to make it appear that necessarily all members of the profession are equally unskillful.

I am aware that human knowledge and skill are limited, and painfully feel my own shortcomings in this respect, but I do not consider I have any right to attempt, in the foregoing manner, to saddle others with my imperfections.

I ask Mr. Hoare—Does he consider anyone has a right to involve others, as above described, in his errors?

Mr. Hoare asks, "Why go to the trouble of conducting post-mortems at all when a definite opinion has been given," or I will put it, when a definite opinion can be formed. I may here state I have always held a post-mortem examination whenever I had an opportunity of so doing, and I am pleased to be able to state that whenever I formed a definite opinion on a case, the cadaveric lesions most satisfactorily corroborated my anti-mortem diagnosis, and frequently I have found most interesting specimens, apart from the ailments for which the animal was suffering, immediately preceding its death, and were in no way connected with its last illness.

Indeed, a fund of knowledge can be derived from post-mortem examinations, especially if the animal has been for some time under the practitioner's observation. In my opinion post-mortem examinations obtain for some a good reputation, and give them confidence in their ability to diagnose cases, and exposes to others their inability to correctly do so, and to both parties should be an incentive to progress in knowledge, the one to uphold his good reputation, and the other to endeavour to gain it.

JAS. MCKENNY, M.R.C.V.S.

"SIR ORACLE."

Sir,

I think the true definition of a Sir Oracle is a man that gives an opinion that can be interpreted in two different ways, or one that ostentatiously makes a statement as a fact that cannot be supported by reason or argument. He is closely allied to the gentleman (described by a certain well-known and esteemed Professor) who makes statements that are "opposed to all science and all authority." Such a man, the professor continued, ought "never to put pen to paper," and as a matter of fact he is wise enough to seldom do so.—Yours truly,

G. MAYALL.

Some of the foregoing has been unavoidably held over.

THE V.M.A. OF IRELAND.—A CORRECTION.

Dear Sir,

At the end of page 268, col. 2, and top of page 269, col. 1, you give the name of Mr. J. P. Machattie as being the winner of the Association's medal. It was Mr. J. P. McNALLY who obtained first place in the examination for the Diploma of M.R.C.V.S. in the Royal Veterinary College of Ireland, and to whom the medal was awarded.—Yours faithfully,

J. J. O'CONNOR, Hon. Sec.

Royal Vet. Coll. of Ireland.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1322.

NOVEMBER 8, 1913.

VOL. XXVI.

"THE RECORD."

We feel that it is due to our readers, and especially to those of them who have enquired on the point, that they should know something of future arrangements. For the present no further change in the management is contemplated. It is an open secret that Mr. Hunting ceased active work in 1907, when he took up the appointment under the London County Council; and for the last four years has contributed only occasionally to our pages, his severe illness, followed by a long period of failing health, rendered that almost a necessity. Those who have worked with him are continuing the work, and his known views on most professional matters will be followed so far as they are not affected by changing conditions of professional work. It is not unlikely that other men may join the literary staff in the near future; and in all respects *The Record* will continue as heretofore. A weekly journal for the profession."

THE INTERNATIONAL VETERINARY CONGRESS.

The report of the meeting of the Organising Committee of this Congress, which we printed last week, reveals both good and bad progress. A great step forward has been made by obtaining recognition of the Congress from the Government. For the State to make a financial grant to any such Congress as this would be contrary to all precedent; and no one hoped that the rule might be broken in our favour. But the Foreign Office is encouraging the Congress and inviting delegates, and has promised to give a reception to them; and this is about as much as could be expected from a British Government. It will increase the number of foreign delegates, and so far make for success.

On the other hand, the Treasurer's report shows that subscriptions have fallen off woefully during the last three months. More than £300 is still required to reach the absolute minimum that has been estimated as necessary; and there is every indication that the Congress will be a record one and the minimum will be insufficient. The Treasurer's report should be read: there are two points in it which cannot be over-emphasised. About £3 will be spent upon each member joining the Congress; and therefore, unless he considerably exceeds his membership subscription of £1, he will be a source of actual loss. Again, the present total of £3,180 has been subscribed or promised by

less than 300 men—that is, more than nine-tenths of us have not yet offered a shilling. When so few of us have brought the Congress to within sight of success, as it now is, surely the great majority will do the little still required to make success assured. It is true that we cannot all afford £3, but almost all can afford a little.

THE PATENT MEDICINE TRADE.

Some years ago *The British Medical Journal* undertook a long series of analyses of patent medicines. The results were published in a small book, which did a great deal of good. The same thing has long been needed in the case of proprietary medicines for animals, and Mr. Hobday and Prof. Lander have done a service to the profession by undertaking it. All the assistance they ask, in their letter published last week, is that members should supply them with unopened samples of the animal medicines most used in their districts—they will do the rest. Practitioners should respond readily to this, and the result may be really valuable. Some may hesitate to send particular preparations on account of the possibility that they have been analysed already, but no doubt the originators would willingly answer queries on that point.

SNAKE BITE (?)

A case which I have been attending recently has caused me some mystification, and I record it in the hope of receiving from your readers either corroboration of my suspicions, or a more satisfactory explanation of such unusual symptoms.

The cow was turned out one afternoon about five weeks ago, on a meadow which sloped down to a more wooded part with a good deal of undergrowth. Next morning the cowman found her laid, and great difficulty was experienced in inducing her to get up and walk home.

The cow moved very stiffly, and the left hind-quarter of the udder was practically black. The other three quarters were quite normal. On arrival home, the cow fell down and did not rise for some days, appearing partially paralysed.

The original diagnosis was cold, but a closer examination of the affected quarter showed a hole about half-way up the teat. It was just as if a piece had been punched quite out, and was approximately the diameter of the ordinary teat opening, which was of course in the usual place.

The cow showed signs of severe systemic disturbance for some days, but eventually, after the

quarter had been injected with Chinosol solution, got much better in general health.

The affected quarter became gangrenous, and after a time the teat, and practically the whole of the gland substance' sloughed away, leaving a large cavity which has now almost healed up.

At no time was there any alteration in the other quarters, and they secreted milk apparently normal in all respects. I am strongly of the opinion that the condition is attributable to snake bite, although nothing definite could be traced.

The peculiar punched-out hole in the teat, coupled with such a severe disturbance of general health, seems distinctly to point to this conclusion.

SYDNEY SMITH, JR.

Lowestoft, Oct, 22nd.

DIAGNOSIS OF TUBERCULOSIS.

Subject.—A red shorthorn heifer, which was suckling a calf. On examination the pulse, temperature, and respirations were normal. She was emaciated and hidebound, had had diarrhoea a few days before my examination. No cough was present, and on auscultation the lungs seemed normal. I proceeded to make an examination per rectum, and could feel some of the grapes on the rumen, as described by Mr. Broad, of Marlborough, in *The Record* of September 27th, 1913.

I advised the owner to report the case, but he refused and sent her directly to the knacker. Post-mortem showed her to be affected with tuberculosis of the peritoneum. I find on reference to Friedberger and Fröhner, Vol. II., page 361, the following method described:—"The presence of tuberculous proliferations of the peritoneum may be proved by introducing into the rectum, or by pushing the hand under the last false ribs."

The refusal of the owner to report the case, and the fact that he had the heifer destroyed there and then, illustrates one of the difficulties in carrying out the recent Tuberculosis Order.

I should like the opinions of the readers of *The Record* whether the owner and myself were liable to prosecution for failure to report. I am certain if I had done so I should have lost my client. Personally, I do not think it was necessary to report this case, as the animal was destroyed at once at the owner's loss entirely.

I should like to thank Mr. Broad, also, for his hint as to rectal exploration in these cases.

"NEMO."

ABSTRACTS FROM FOREIGN JOURNALS.

ENORMOUS HÆMATOMA OF THE SPLEEN IN A DOG,

Prof. Joest, in an annual report of the work of the Royal Veterinary High School of Dresden, records the following case. The subject was a male mongrel dog, about 53lbs. in weight, which was destroyed on account of a tumour in the abdominal cavity, associated with abdominal dropsy.

Post-mortem, the abdominal cavity was found to contain from 2 to 3 litres (roughly from 3½ to 5½ pints) of a reddish transudate. The ventral surface of the spleen was occupied by a gigantic tumour-like body, exceeding the size of a man's head, weighing about 11lb., and of an irregular knobby shape. The colour of the tumour was dark red, and its consistence was firm. Its upper surface was united to the omentum. The size of this body caused the spleen, which was otherwise normal, to appear like a small appendage of the tumour.

Upon section, this apparent tumour proved to be not a tumour at all, but a hæmatoma. It contained coagulated blood, which was older at its peripheral parts and fresher in the central portions.

Joest's view of the case is that an effusion of blood had taken place gradually, till it amounted to more than a quarter of the actual body weight. The total quantity of the effused blood was about triple that normally present in the animal.—*Munchener. Tier Woch.*

METALLIC LIGATURE OF THE UMBILICAL CORD.

Hursch maintains (*Schweizer Archiv.*) that as a general rule the metallic ligatures employed in surgery present one great advantage over silk threads, etc., viz., that by reason of their impermeability, they oppose the passage of germs into the wounds. Hursch has used metallic ligatures with very good results for the ligation of the umbilical cord. By this method he not only uses an aseptic apparatus, but also, on account of the powerful constriction which it affects, he hinders the passage of external germs into the umbilical vessels. Properly applied, the metallic ring acts upon the umbilical cord much as castration clamps upon the spermatic cord.

Hursch uses a special pair of pincers, between the teeth of which he places a metal ring. He passes the umbilical cord into the ring, and compresses the latter with the pincers until it assumes the form of a clamp about 3/5 inch long by from 1/12 to 1/8 inch wide. Immediately after applying the apparatus, he divides the cord very close to the inferior face of the clamp, and paints the region with an alcoholic solution of pyoktannin.

The procedure is a very quick one, and has been most favourably received by owners. Hursch considers that the simple ligature of the umbilical cord, as it is generally practised by breeders, presents many more disadvantages than advantages, for it very often entails complications from infections of the cord. He has found that, in regions where the ordinary ligation of the cord has been practised, half the foals have shown infection of the cord, and the farmers in consequence have given up the method.

It remains to be added that a ligature is dangerous when it is not applied very near to the abdominal wall, because it then exposes the portion of the cord situated above it to infection. On the other hand, it is advisable to abstain from washing the cord with antiseptics, because these impede the rapid mummification of the cord.—*Annales de Méd. Vét.*

EXTENSION OF AN INFLAMMATION OF THE MIDDLE EAR INTO THE CEREBELLUM IN A SHEEP.

Erhardt, a veterinary practitioner of Hersbruck, records the case of an ewe which came under treatment on account of the following symptoms. The head was continuously held low, and inclined to the left. The ewe maintained herself on her limbs with difficulty; and, if pushed towards the left, she fell to the ground and made convulsive movements with both fore feet.

The probable diagnosis arrived at was that of a cœnurus cyst; which seemed likely, from the symptoms shown, to be deeply situated. An exploratory trephining was therefore decided upon.

The skull was trephined about four-fifths of an inch from the medial line, at about the highest point of the left cerebral hemisphere. No trace of a cyst could be found. The ewe was then immediately slaughtered, and a post-mortem examination was carried out. This revealed an abscess in the left half of the cerebellum, filled with greenish pus, and in connection with the osseous auditory canal.

The owner then imparted the information that the ewe had been bitten on the ear by a dog some weeks before, and had afterwards shown an inflammation of the ear. The abscess was therefore the result of an extension of inflammation from the middle ear.—(*Munchener Tier. Woch.*)

TWO CASES OF TUBERCULOSIS OF THE BRAIN.

Bergschicker, of Bartin, records the following cases;

An ox about six months old was operated upon on account of entropium of one upper eyelid, with a consecutive chronic keratitis. Healing by first intention took place, and the stitches were removed on the eighth day. The keratitis seemed to be clearing up.

Eight weeks later, Bergschicker found the ox with his body in an attitude resembling that of tetanus, and pressing his head against the wall. The cornea of the eye which had been operated upon had now cleared to some extent; and its inner side was seen to be beset with small nodules, doubtless of tubercular origin. Bergschicker diagnosed generalised tuberculosis, especially affecting the head and cerebral meninges. The animal was accordingly slaughtered.

Post-mortem, most of the organs were found free from tuberculosis, the spleen alone showing small isolated tubercular nodules. The carcass was well nourished. A moderate number of tuberculous centres, up to the size of a pea, were found in the pulmonary and mesenteric lymphatic glands.

All the membranes of the eye and the cerebral membranes, were beset with tubercles the size of millet seeds. The cerebral substance was quite free from tubercles.

It was impossible to decide whether the entropium had been the primary affection, and the vascularisation accompanying the consecutive keratitis had favoured a tubercular infection of the eye,

or whether the process had been exactly the reverse, and the eye had been infected from the interior of the body.

The latter view seems probably the correct one. At any rate, entropium and a diffuse opacity of the cornea were all that could be seen at the time of operation.

The second case was a cow, about ten years old, which had given birth to a living calf four weeks before her time. The after-birth had been retained, but this was said not to have specially influenced the general condition. Fourteen days after calving the cow was found in the morning lying apathetically with her head turned upon her neck; and, when the owner attempted to get her up, she fell into violent clonic-tonic convulsions of all the muscles of the body.

Bergschicker saw her ten minutes after the first seizure, and found her in the same condition. The frequency of the heart and respirations was increased. The temperature was normal. The convulsions continued to become more violent, without seeming to commence from any distinct group of muscles, while the pauses between the spasms gradually became shorter. Bergschicker was at a loss for a diagnosis, mentioning epilepsy, cerebral tumour and cerebral hæmorrhage as possibilities. The cow was slaughtered after an hour. The blood was almost black, and spurted with great violence from the cervical vessels at slaughter; and the contraction of the muscular system did not relax till some minutes after bleeding had been completed.

Post-mortem, a sapræmic metritis was found. In addition, the parietal pleuræ and parietal peritoneum, with the organs they contained, showed a moderate number of caseous tubercles the size of large peas. The under side of the diaphragmatic pleura bore a larger tuberculous growth. One mediastinal gland showed a caseous tuberculous nodule the size of a large millet seed. The remaining organs were free from tuberculosis, with the exception of the cerebellum, in which there was a caseous tuberculous centre larger than a pea, pressing upon the corpus medullare.—(*Berliner Tier. Woch.*)

W. R. C.

LIST OF ACCREDITED VETERINARY COLLEGES, U.S.A.*

The following is a list of accredited veterinary colleges, graduates of which are eligible for the Civil Service Examination for the position of Veterinary Inspector in the Bureau of Animal Industry, under the terms of the regulations governing entrance to the Veterinary Inspector Examination (Bureau of Animal Industry Circular 150):—

Alabama Polytechnic Institute, College of Vet. Med.
Chicago Veterinary College.
Cincinnati Veterinary College.
Colorado State College, Division of Veterinary Medicine
George Washington University, College of Vet. Med.
Grand Rapids Veterinary College.
Indiana Veterinary College.
Iowa State College, Division of Veterinary Medicine.

* This, and two following abstracts are from the Annual Report, Bureau of Animal Industry, Dept. of Agric., U.S.A.

Kansas City Veterinary College.

BRAHMIN CATTLE IN TEXAS.

Surra was found in an importation of zebu cattle shipped from Bombay, India, April 27th, 1906, but it was not allowed to escape from the quarantine. This occurrence not only served the purpose of an additional test of the efficiency of our international quarantine service, but at the same time gave the bureau actual experience with this disease, which from time to time has wrought such havoc among stock, especially horses, in oriental countries. It appears that over 30 years ago Mr. A. H. Pierce introduced into Southern Texas a number of so-called Brahmin cattle from India which were successfully crossed on the native cattle, with the result that their progeny were relatively free from ticks, while the native stock in the same pasture would be literally covered with these pests. As a consequence the Brahmin grades thrived under the same conditions which served to deplete the native stock. They not only withstood the semi-tropical weather conditions of the Gulf coast section, but their thin, tough skin, very short hair, and the seeming repugnance of their sebaceous secretion of insect life, rendered them immune to heavy tick infestation, while at the same time they were immune to Texas fever, their natural *habitat* being a tick-fever country.

PHENOLIZED BLOOD IN INOCULATIONS.

The use of carbolized or phenolized blood, as described in the last annual report, has been continued during the year. The later results confirm the earlier observations in showing that the virus of hog cholera may remain in contact with comparatively strong solutions of phenol for weeks without noticeable impairment of its virulence. There seems to be little doubt that phenolized blood will gradually come into general use in connection with the "simultaneous method," as the presence of the phenol prevents the development of putrefactive bacteria and does not destroy the virus of hog cholera. This will enable practitioners to keep virus on hand for a reasonable length of time.

Considerable study has been given to the effect of different preservative agents on the virus of hog cholera as contained in the blood of sick hogs. In addition to the con-

tinued study of phenol, much attention has been devoted to thymol and formaldehyde. The results with regard to these, however, are not yet complete. Aside from the desirability of having some means of preserving the virus for use in simultaneous inoculations, it is also desirable to have some means of preserving disease-producing blood which is to be used later for hyperimmunization. Phenol is not satisfactory for this purpose, but it is hoped that some efficient germicide which is efficient against ordinary bacteria, but which does not materially affect the virus of hog cholera, will be found suitable for this purpose. Some attention has also been given to different preservatives for serum. These observations are not yet complete.

F. E. P.

ANNUAL REPORT OF THE CIVIL VETERINARY DEPARTMENT, NORTH-WEST FRONTIER PROVINCE, FOR THE YEAR ENDING 31ST MARCH, 1913. [ABSTRACT.]

Under the head of "General Administration," the report states that "Mr. Woodley held the appointment of the Superintendent, Civil Veterinary Department, North Punjab and North-West Frontier Province, throughout the year 1912-13. Mr. Woodley was on tour in the North-West Frontier Province for 105 days, and travelled 2094 miles by rail and 1419 by road. He also held charge of the North Punjab Circle, and was on tour in that Province for 57 days.

The Superintendent inspected all the veterinary hospitals (15), and the offices of all the itinerating veterinary assistants in the Province.

Nine tonga lines were also inspected.

He attended and acted as a member of the Judging Committee at the following fairs and shows:—Haripure Cattle Show, Peshawar, Kohat, Bannu and Dera Ismail Khan Horse and Cattle Shows.

The Superintendent personally checked inoculations on three occasions in the Peshawar District, and once in the Hazara District. He attended an outbreak of surra in the Malakand Agency. He also checked the work of veterinary assistants in various districts. He interviewed the Revenue Commissioner twice for discussing official matters. As usual, during the course of his tours, the Superintendent interviewed District and Agency officers with a view to discussing veterinary matters, and inspected bulls and stallions where they were.

He also made an extended tour in the Hazara District in connection with the merino sheep-breeding.

He made the following purchases:—Three donkey stallions from the Hissar Farm for the Province, two bulls from Chakwal for the Hazara District, and twenty dumba sheep for the Civil Veterinary Department, Eastern Bengal and Assam.

TREATMENT OF DISEASES.

During the year under report 14,045 cases of epidemic diseases were reported, of which 3496 proved fatal, compared with 19,674 cases and 5245 deaths in the previous year.

One hundred and twenty-four pathological specimens were received from the subordinate veterinary staff, and they all were examined by the Superintendent, as compared with 51 for last year.

CONTAGIOUS DISEASES—EQUINE.

These were reported from all the districts and agencies. In all 368 cases were reported, of which 11 proved fatal, compared with 392 cases and 19 deaths in the previous year. These figures relate to non-selected districts only.

Glanders.—Five cases of glanders occurred against 11 last year. The diagnosis was confirmed in three cases,

and the animals were destroyed. The remaining two died before they could be examined by a veterinary practitioner.

One case of anthrax was reported from the Kohat District. The diagnosis was confirmed microscopically by the Superintendent.

Surra.—Twelve cases were reported during the year under report, of which two were reported to have died. Diagnosis was confirmed by microscopic examination.

Other Contagious Diseases.—Under this head 350 cases were reported, of which three died, against 358 cases and eight deaths last year. These include mange, strangles, tetanus and bursati.

CONTAGIOUS DISEASES—BOVINE.

During the year 1545 deaths and 9890 cases were reported, against 1829 deaths and 11,509 cases last year.

Rinderpest appeared in four districts of the Province. In all 1755 cases were reported, of which 708 died, against 1394 cases and 707 deaths last year. The disease was most prevalent in the Peshawar District. During the year 15,266 animals were inoculated in 61 outbreaks against 8,848 animals in 38 outbreaks last year. Rs. 2600 were paid by Government on account of cost of anti-rinderpest serum.

Hæmorrhagic Septicæmia occurred in five districts. 637 cases were reported, of which 575 proved fatal, against 997 cases and 888 deaths last year. 731 healthy animals were vaccinated against this disease in nine villages where it usually occurs. Last year 189 animals were vaccinated in twelve villages.

Foot-and-Mouth Disease occurred in four districts and one agency. Kurram Agency suffered the most. In all 7,117 cases were reported, of which 15 died, against 8,827 cases and 48 deaths last year. As usual, the necessary preventive measures were adopted by the subordinate Veterinary staff.

Black quarter was reported from four districts; 138 cases occurred and 124 proved fatal compared with 194 cases and 166 deaths last year. 2,700 healthy animals were vaccinated against black-quarter. None were performed last year. The disease did not re-appear in any of the villages where the vaccinations were performed, hence the efficacy of the vaccine cannot be judged.

Anthrax. No cases in cattle were microscopically diagnosed during the year.

Other Contagious Diseases. 243 cases of other contagious diseases (including mange, tuberculosis, tick fever, tetanus, gilliar, and actinomycosis) were reported, of which 123 died.

CONTAGIOUS DISEASES—OTHER ANIMALS.

Disease.	Attacked.	Died.
Rinderpest	2255	1587
Foot-and-Mouth	732	35
Hæmorrhagic septicæmia	193	190
Anthrax	2	2
Other contagious diseases*	555	126
Total	3737	1940

Compared with 7773 cases and 3397 deaths last year.

* Mange, rabies, fowl cholera, distemper, liver rot, camel-pox, sheep-pox, and contagious pleuro-pneumonia.

Treatment of disease on tour. During the year 1377 villages were visited by Veterinary assistants on tour, and 10,944 animals were treated. Last year 1352 villages were visited and 12,671 animals treated. 517 castrations were performed, chiefly in equines, as compared with 584 last year.

VETERINARY HOSPITALS.

During the year there were 19 Veterinary hospitals in the Province, and the total number of animals treated in these institutions was 49,465. Last year 48,134 cases were treated in the same number of hospitals.

Peshawar District. Peshawar Hospital was practically completed during the year, but additions are still required. When complete it will probably be the finest hospital in Northern India. Charsadda Hospital is complete. Mardan, Swabi, and Nowshera still require operation and cattle sheds.

Hazara District. Abbottabad Hospital.—Dog kennels and segregation stables are required. Mansehra Haripur also require segregation stables, but are otherwise complete.

Kohat District. Kohat and Hangu hospitals are complete. Teri Hospital requires operation, cattle shed and stallion stables.

Bannu District. Bannu Hospital is complete. Sarai Naurang Hospital still requires an operation shed.

Dera Ismail Khan District. Dera Ismail Khan Hospital is complete. Chaudhwan Hospital requires segregation and stallion stables. A new hospital is required at Tank, as the original one was required for the Border Military Police, and the work is now being carried on in a temporary building.

Malakand Agency. Dargai Hospital is sufficient for the requirements, but a stallion stable is wanted.

Kurram Agency. The Parachinar Hospital is still in need of contagious ward and dog kennels.

Tochi Agency. Miranshah Hospital is sufficient for the requirements, but a separate stallion stable is indicated.

On the whole the progress of construction has been satisfactory, and in a few years all the hospitals should be complete, but many will annually require extensions. The treatment at all the hospitals is free.

[Space does not permit any details under the heads of Breeding Operations, Fairs and Shows, Subordinate Establishment. Under Expenditure, the annual cost is put at "Rs. 55,045, against Rs. 39,682 in the previous year. The increase appears chiefly due to the expenditure connected with the horse and cattle shows held during the year under report."]

GENERAL REMARKS.

The results on the work of the year may be considered as most satisfactory. A similar remark was made last year, but during the year under report the number of animals attacked with contagious diseases has decreased by 5,629 cases, and the mortality therefrom by 1,749. Breeding operations, chiefly horse and sheep, have improved and increased.

Preventive inoculations and vaccinations show a large increase on previous years, and in most places the people readily adopt it. In some cases it appears that inoculations were begun too late, and by that time most, if not all, the susceptible animals had died or taken the disease and only the immune animals were left, consequently in such cases inoculation is of little use. Reports of outbreaks are often received too late, and the veterinary assistant through ignorance or carelessness inoculates when it is unnecessary, and hence a certain amount of serum is wasted. Statistical results of inoculations in these cases look very well on paper, but probably they would be different if the inoculation had been started at the very beginning of the outbreak. More promptness in reporting by the patwari, the early performance of inoculation, and strict superior supervision are the three great factors necessary for better results.

Horse-breeding is flourishing, and great keenness is shown by the people of Bannu, Peshawar, and the

Kurram Agency. The standard scale of horse stallions has been increased by one in the Kurram Agency. Bannu and Dera Ismail Khan also require an extra stallion each. The Political Agent of the Kurram Agency intends holding an annual horse and cattle show in future. This Agency is very subject to the ravages of cattle diseases, and consequently the veterinary assistant at Parachinar is frequently having to go on tour. The Superintendent is of opinion that an itinerating veterinary assistant is urgently required for this work with his headquarters and a branch dispensary at Saddar or Alizai. A new stallion stable consisting of one horse and one donkey, has recently been opened at Alizai.

The thoroughbred Australian stallion which was supplied to the Bannu District through the Quarter-master General, was found on arrival to be hereditarily unsound, and consequently he was not allowed to be used for stud purposes. An enquiry is being made by the Deputy Commissioner.

Three donkey stallions were supplied by the Hissar Farm during the year, at a cost of Rs. 600 each; the price previous to this used to be Rs. 450. They were a poor lot of animals, and the only ones available at the time. Donkeys similar to this lot can be got in the local market for about Rs. 150 each. One of the Hissar bred donkeys received in February, 1911, had to be cast as he refused to cover, and one out of the new lot received in December, 1912, is a similar failure. This is the third case which has come under the notice of the Superintendent within the last year.

The Superintendent toured in Kaghan during last June and July in connection with the merino sheep-breeding experiments, and submitted his report on the same to the Revenue Commissioner. The breeding results were most encouraging and satisfactory. There were then close on 300 cross-bred lambs. The Dhariwal Woollen Mills Company, to whom a sample of the cross-bred wool was sent, expressed the opinion that it was the finest sample they had yet seen in India. The question of opening up a wool trade with Kaghan is being considered by this company, and they were kind enough to offer Rs. 200 for prizes in connection with a sheep show to be held during the coming year. This offer was accepted and agreed to by the Deputy Commissioner, Hazara, but unfortunately the show had to be cancelled, as the Superintendent, Civil Veterinary Department, could not perform the journey owing to objections from the Accountant-General's Office. The matter is most regrettable, as the experiment should receive every encouragement in the initial stage, which has so far proved very promising.

The Superintendent again records the unsatisfactory way in which he has to perform his work and carry out inspections in such a hurried manner owing to the large extent of his circle both in the Punjab and the North-West Frontier Province, but he notes with pleasure that a separate officer will probably be sanctioned during the coming year for the North-West Frontier Province alone.

V. DE V. H. WOODLEY.

*Superintendent, Civil Veterinary Department,
North-West Frontier Province and North Punjab.*

The covering letter by Lieut.-Col. C. B. Rawlinson, Agent to the Governor-General, N.W. Frontier Province, concludes:—

"The question of the appointment of a whole-time Superintendent for this Province is still under consideration by the Government of India; it is understood that sanction to the appointment will be shortly announced.

"In conclusion the Chief Commissioner has much pleasure in acknowledging the excellent services rendered by Mr. Woodley during the year."

ANNUAL REPORT OF THE VETERINARY INSPECTOR NEWCASTLE-ON-TYNE FOR THE YEAR 1912.

[ABSTRACT]

TO ALDERMAN SIR HENRY W. NEWTON, J.P., L.F.P.S.,
Chairman of the Executive Committee under the
Diseases of Animals Acts of the Corporation of New-
castle-upon-Tyne.

Sir,—I have the honour to present this Annual Report, on the duties performed under the Contagious Diseases of Animals Acts for the year ending Dec. 31, 1912.

DISEASES OF ANIMALS ACTS, 1894-1912.

During the past twelve months nineteen outbreaks of contagious disease (as defined by the Acts) occurred amongst the animals within the City, as compared with three during the previous year.

[After remarks upon anthrax and the scope of the Tuberculosis Order, 1913].

Foot-and-Mouth Disease. On Monday, July 1st, the disease was discovered in several of the herd of 36 cattle in a field at Benwell. The foot-and-mouth disease restrictions were about to be removed and the district entirely freed on or about the 20th September. On the 17th September, however, the Veterinary Inspector was called to a farm in the Walker district to examine some swine which were ill. Several of these were found to be suffering from foot-and-mouth disease.

No new swine had been brought to the farm at Walker for at least seven months prior to the outbreak, yet the disease occurred and spread rapidly amongst them before any cattle were obviously ill. A new cow had been purchased from the Hexham district only a week prior to this outbreak. When the owner purchased the cow at Hexham he was for some considerable time in close company with another farmer who, it subsequently transpired, had a number of cattle at home suffering from foot-and-mouth disease. There are reasonable grounds for suspecting that, in this case, the disease was conveyed, by the farmer's clothes, from the infected cattle and transmitted by the second farmer to his premises at Walker, for on returning home he immediately handled some of his young pigs. Within the next four days several of these young pigs were reported ill, hence the discovery of the outbreak. The restrictions were finally removed by an Order to that effect on the 26th November, 1912, the district being thus free from restrictions as to the movement of cattle for the first time since the last day of June, 1912.

During the period that the Durham and Northumberland and the Newcastle and District (Foot-and-Mouth Disease) Orders of 1912 were in operation, 2,800 licences were granted within the city for the removal of stock; and 125 duplicate licences were received and inquiries made in accordance with the Orders under which they were granted.

Modern Abattoirs. During the period of operation of the Foot-and-Mouth Disease Orders requiring animals to be licensed for removal from the cattle market direct to slaughter houses within certain areas only, there was ample evidence of the necessity of Public Abattoirs wherein cattle should be slaughtered and the carcasses subjected to official inspection. This would be valuable not only from the Agricultural point of view by tracing the source of animal diseases, but also from the Public Health point of view; e.g.—a number of uninsured cattle (cows) were slaughtered within the city by country butchers, several being found to be extensively diseased (tuberculosis), and were condemned and destroyed as unfit for food. Had these animals not been slaughtered within the city, it is almost certain that their diseased carcasses would have been disposed of for human con-

sumption in precisely the same manner as is well known to many traders in cattle of that class.

Swine Fever.—During the year one outbreak of swine fever occurred in a herd of 22 swine on a farm within the city. The premises were promptly placed under movement restrictions and dealt with in accordance with the requirements of the Swine Fever Order of 1908. During the year, 1375 duplicate licences, granted under the Swine Fever (Regulation of Movement) Order of 1908, have been received from various Local Authorities and the necessary inquiries made concerning the swine so moved. Within the same period 9343 licences have been granted within the City for the removal of swine.

Parasitic Mange. During 1912 sixteen outbreaks of parasitic mange occurred within the city, some 35 horses being found affected with the disease.

Exportation of Horses. For the purposes of the Exportation of Horses Order of 1910 (No. 2) and the Horses (Importation and Transit) Order of 1912, the export animals, vessels, fittings and the cleansing and disinfecting, etc., of the latter, have been regularly inspected. Suggestions for the improvement of embarkation of the animals and the prevention of injury to animals' heads whilst on board (overhead anti-concussion beams) have been made, and are now under consideration by the shipping company. During the year 1912 there were 3,625 horses presented at the quayside for examination prior to embarkation. Of these 119 were rejected as being unfit, permits for the remaining 3506 being granted by the Board's Veterinary Inspector.

The Sheep-Dipping (Scotland and North of England) Order of 1907. Under the above Order certificates have been granted from time to time (some 50 in all) to persons removing sheep to other markets.

Vessels arriving from other parts of the Kingdom. During the year 51 visits were paid to vessels arriving coastwise for the purpose of the Animals' (Transit and General) Order of 1912. The numbers of animals landed at the quayside during the year were 561 horses, 607 cattle, 1,095 sheep, 7,011 swine, and 1 calf.

Horse and Cattle Fairs and Weekly Horse Sales. For the purposes of the Diseases of Animals Acts generally, the cattle and horse fairs on Town Moor and in the Cattle Market have been regularly visited, whilst the weekly horse saleyards and auction marts have been visited regularly for the purposes of the Glanders and Farcy Order of 1907 and the Parasitic Mange Order of 1911.

Cattle Market. The weekly cattle markets have been regularly visited, and the animals subjected to regular and frequent inspections. The following table shows the numbers of cattle, etc., exposed for sale therein.

Year.	Cattle.	Calves.	Sheep.	Swine.
1892	105,088	7,192	373,639	30,798
1902	100,358	6,928	354,636	37,918
1912	48,222	4,646	227,046	32,562

In 1910 there were 77,347 cattle, and in 1911, 70,337.

Cattle and Licensed Pig Lairs. There are thirty cattle and licensed pig lairs within the city, and for the requirements of the Swine Fever Order of 1908, and the Market and Sales Order of 1910, 1,134 visits to them were paid during the year.

Railway Waggons and Cattle Docks.—For the requirements of the Animals' (Transit and General) Order of 1912, the Railway Cattle Docks have been regularly inspected (152 visits being paid) during the year. The same remarks apply to the railway waggons.

The Late Alderman J. Armorer Baty. I wish here to record my appreciation of the great encouragement, support, and sound advice given to me from time to time by Alderman Baty, the late Vice-Chairman of the

Sanitary Committee, and as Chairman of the Cattle Trade Committee. In the work of combating animal contagious diseases within the city, the late Alderman Baty rendered a service, extending over many years, of which any local authority may feel proud.

Your obedient servant,

THOMAS PARKER, F.R.C.V.S.

Vety. Inspector and Inspector of Meat, etc.

Town Hall, Newcastle-upon-Tyne.

June 30th.

VICTORIA VETERINARY BENEVOLENT FUND.

The quarterly meeting was held at 10, Red Lion Square, London, on Thursday, October 9th. Present: Messrs. Trigger, Garnett, Slocock, Spicer, Wharam, Dunstan, Sumner, West, and the Secretary.

The minutes of the last meeting were read and confirmed.

THE SECRETARY'S REPORT.

I have only a little matter to report for this quarter.

Financial. I estimate our expenditure for the following three months to be about £85 for relief. We have in the bank a sum to meet this of £80.

There will be dividends on consols, and Norwich Corporation stock some £27.

This will be all the money available to pay for printing, postages, and incidental expenses for the past year.

Included in the sum of £80, is the sum of £27 donations, which, according to Rule 4, must be invested.

The subscriptions in arrear amount to £40.

You will see by this statement that our financial position is by no means satisfactory. I hope, however, it may be possible to obtain a sufficient number of new subscribers to help us over our difficulties.

Old Recipients. I have received communications with reference to one of our recipients, and am making inquiries as to the justification of the contents. In the meantime I have suspended the monthly grant.

During the following three months it is my intention to again verify the position of all our recipients. At the present time I think all grants should be continued.

In the case of Mrs. W., I have letters from Mr. Reavy pointing out the urgency of a suitable education for the children, and would suggest that the grant in this case might be increased from 5s. to 10s. per week. You will remember this case was referred to us by the Executive Committee in Ireland.

I have had one further application for relief, which, after making every enquiry, I cannot recommend for the consideration of the Council.

I am in communication with the National Veterinary Benevolent and Defence Society, and in no case is there any overlapping, but as a matter of fact a cordial co-operation.

I must still express a wish that every effort be made to give publicity to the work of our Fund, and beg of subscribers to remit the subscriptions now in arrear to save further expense in literature and postage.

On the motion of Mr. Garnett, seconded by Mr. Sumner, the question of the continuation of a grant to one of the old recipients was held over pending further enquiries to be made by the Secretary.

An application for an increased grant to one of the old recipients was duly considered. Proposed by Mr. Wharam, and seconded by Mr. Slocock, the financial position of the Fund was such that no increase could be made in the grant.

The report of the Secretary was confirmed, subject to the foregoing resolutions.

Correspondence from Colonial members, Messrs Reakes and Amos, was read.

The members of Council cordially recognise the kind offers of help, and desired the Secretary to keep in touch with the correspondents with a view to the development of further help and assistance from abroad.

LIST OF NEW SUBSCRIBERS FROM JULY, 1913.

	£	s.	d.
Balden, John, Stocksfield-on-Tyne	5	0	0
Amos, S. T. A., Durban	2	2	0
Barnes, C. T., Cheadle, Stoke-on-Trent	10	6	
Baker, A., Lismacue, Bansha, Ireland	10	6	
Arnold & Son, Giltspur Street, London	2	2	0
Grypsperdt, L. G., Croydon	10	6	
Heney, Fred. A., Dublin, increased to	1	1	0
Blackwell, W. E., Towcester, Northants	10	6	
Heatley, T. G. Woodbridge, Proceeds of Bowls Tournament	5	4	6
Waters, W., Blofield, " " "	2	0	0
Wilkinson, H. E., Martham. Tournament for the Victoria Veterinary Benevolent Bowling Cup	1	5	0
Smart, W. W., (Donation)	1	1	0

SCOTTISH METROPOLITAN VETERINARY MEDICAL SOCIETY.

A meeting was held at the Royal (Dick) Veterinary College, Edinburgh, on Saturday, 25th October, at 3 p.m. The members present were: Professors J. R. U. Dewar, A. Gofton, A. Wilson, and T. C. Matheson, Edinburgh; Messrs. A. McKenzie, Kirkcaldy; J. Cameron, Jun., Berwick-on-Tweed; J. Aitken, Jun., Dalkeith; A. Baird, Edinburgh; T. M. Inglis, Forfar; J. P. Hamilton, Dundee; J. Storie, senr., East Linton; J. Riddoch, D. S. Davidson, J. L. Cormack, Edinburgh; J. McFarlane, Doune; T. P. Young, Leith; and James Henderson, Hon. Sec. Visitors: Messrs. Wm. Mitchell, Wm. Peggie, and Dr. McLeod.

Apologies for absence were received from Professor Bradley, Messrs. J. G. Reynard, Alex. Wallace, J. Peddie, P. Wilson, Wm. Anderson.

A letter was received from Mr. F. W. Garnett stating the urgency for subscribing to the funds for the Tenth International Veterinary Congress.

Prof. GOFTON proposed that this year we, as a Society, should subscribe the sum of three guineas.

This was seconded by Principal Dewar, and agreed to.

ELECTION OF OFFICERS.

President.—Mr. John Riddoch, proposed by Mr. Peter Wilson, and seconded by Principal Dewar.

Vice-Presidents.—Prof. Gofton and Messrs. Peter Wilson and J. Storie, Sen., proposed by Mr. A. Baird, seconded by Mr. J. Aitken.

Hon. Secretary and Treasurer.—Mr. James Henderson, proposed by Mr. A. Baird, seconded by Principal Dewar.

Auditors.—Messrs. A. Baird and J. Riddoch, proposed by Mr. J. Aitken, seconded by the Secretary.

Council.—Prof. Bradley, Messrs. R. Reid, A. Baird, and T. M. Inglis, proposed by Prof. Gofton, seconded by the Secretary.

Mr. WM. PEGGIE, of Biggar, was nominated for membership by Mr. Peter Wilson, seconded by Principal Dewar.

MUTABILITY OF THE TUBERCLE BACILLUS.

Dr. ALEX. JAMES.

When I promised your Secretary to read to you to-day this paper on the "Mutability of the Tubercle Bacillus," I had in my mind an incident which happened here in Edinburgh a good many years ago. It was in 1899, some years after Koch had given to the world the story of his detection of the tubercle bacillus, and of his recognition of it as the factor of consumption in the individual, and some years also after the view that this tubercle bacillus and its transmission from person to person, was practically the sole factor of the disease, consumption, in the community. Our municipal authorities, ever on the alert for measures to promote public health, had asked some of us medicals to meet with them, and to discuss what might be done by the municipality to prevent, or at any rate to lessen, this spread of infection.

Accordingly, along with some dozen others, I found myself before the Public Health Committee. I need not recapitulate all that was said that afternoon, it is all minuted and printed, but I wish to tell you that in connection with the question of infection from milk, and from person to person in consumption, one thing which I said was, "You may kill off every tuberculous cow, you may banish every phthisical patient, the conditions under which cows and people live remaining the same, you will have the disease back again as bad as ever in a few months." This statement, I remember, came as something like a shock to many of those around me, but now after the lapse of all these years, I have to say that I am still practically of the same mind.

Here I would point out that there is no one more willing than I to acknowledge the wisdom of Faraday's saying, "In knowledge, that man only is to be contemned and despised who is not in a state of transition." "Nor is anything more adverse to accuracy than fixity of opinion."

I am well aware of the truth of all this, but I would point out that in knowledge, as in morality, we have had big and broad and wise principles handed down to us as convictions from the remotest times, principles the wisdom of which is such that they are true and right for all times, and that if in what we hear or see, or are called upon to do we recognise that a violation of these principles is entailed, it is well for us as for our fellow men that we, figuratively speaking, call a halt.

To pass from generalities to particulars, what I meant then, and what I maintain yet, is that the tubercle bacillus is an organism, not specially created by Providence to be a source of suffering and death to man, but simply the virulent transformation which takes place in a harmless and almost certainly useful organism, when by man the principles which Providence has ordained as necessary for the maintenance of a healthy and good life are being violated. This can be illustrated perhaps most aptly by the pneumo-coccus, and the disease pneumonia.

As you all know, the pneumo-coccus is in the mouth of practically every human being, and so long as the individual is leading a healthy life in healthy surroundings, it is performing there a useful function. But if, as the result of ignorance, slothfulness, improvidence or excess on the part of that individual, or of the selfishness, greed, recklessness, or vice on the part of his fellows, the maintenance of good health in face of the ordinary strains and exposure of life is rendered impossible; then in that individual the harmless and useful pneumo-coccus is very likely to become, as regards him, virulent, and the disease pneumonia, and often death a result.

What is true of the pneumococcus and pneumonia is true of many other organisms and diseases as well. But at present we have to consider it only with reference to the tubercle bacillus and tubercular disease.

To this I would now direct your attention, but before going into particulars, let me endeavour to clear away some difficulties which might at this stage seem to militate against what has just been said. When I say, as I have said, that—as the result of certain circumstances, &c., the useful and harmless pneumococcus is very likely to become as regards that individual virulent, and to cause disease and often death, I do not for a moment infer that that individual must be the sole sufferer. I frankly admit that should that individual fall ill with pneumonia, and should he be living among people whose health is below par from causes akin to those which have brought on his own disease, and should he and they be living in an environment which is crowded and insanitary, then it is not at all unlikely that his disease may spread among them by infection. We know, for example, that in many parts of Russia the disease scurvy is looked upon as an infectious disease, and when we reflect that in those parts there are times during which whole village communities are, through privation and exposure, living on the verge of developing the disease, it is quite comprehensible that the malady, having broken out in one individual, this case will be followed by a whole crop of others, just as a conflagration will follow the ignition of one in a bundle of dry sticks which by being constantly rubbed against each other are becoming hotter and hotter. Yet, although we must admit that there must be instances in which isolation of a scurvy patient might be of advantage, we can never assert that we shall stamp out scurvy by efforts to isolate and stamp out the organism on which it undoubtedly depends.

And now as regards the tubercle bacillus, and its mutability. As you are all aware, since Koch demonstrated his acid-fast bacillus, in human and bovine tubercular lesions, it has been shown that acid-fast bacilli, showing very similar anatomical characters are really widely spread organisms. As well as the human and bovine, we know of the bacillus in mammals, and in the bird, the fish, and the reptile. We know also of the butter bacillus, the smegma bacillus, the dung, the timothy and Johne's bacillus, and others.

It was pointed out by Bacon long ago that among men two types of mind can usually be recognised, one best fitted to see differences, the other best fitted to see resemblances. In this connection it is, I think, not far from the truth to say that the laboratory worker, working with microscope and culture tube, within the four walls of his laboratory, is likelier to represent the first type, and the clinician, working among all sorts and conditions of men and animals, and over wide areas is more likely to represent the second. Keeping those points in mind, I would at this stage venture to assert that whilst on the one hand, no one may have been able to transform a smegma or a timothy into a human or a bovine bacillus to the satisfaction of the laboratory worker, yet on the other hand, that the tubercle bacillus, human or bovine, shows such infinite variations as regards its anatomical characters and pathological effects, that the only satisfactory attitude which the clinician mind can assume is to believe that the human and bovine and many other bacilli are practically all blends of one common stock.

We are told for example, as regards differences between human and bovine tubercle that whilst human tuberculous material injected in rabbits generally produces small discrete lesions on the organs, which tend to retrogress, bovine tuberculous material induces a progressive disease with large caseating masses. Yet we have it that the Royal Commission of 1908 found—

(1) That with bovine tuberculous tissue into bovines, in some cases a progressive and rapid tuberculosis spread, whilst in others a limited retrogressive tuberculosis would result. Also

(2) That with human tuberculous tissue divided, however, into two groups, because taken from different tuberculous parts, one group would in bovine give rise to a fatal generalized progressive tuberculosis, and the other group for the most part to a retrogressive tuberculous lesion. That is to say that the differences which are described as existing between the pathological effects of human and bovine tubercle in the rabbit are no greater than the differences found to occur between two different blends of human tuberculous tissue when injected into the cow.

Of course it will be said by the laboratory observer of differences, that whilst this difference in the action of these two groups or blends of human tuberculous tissue on the cow is accidental and occasional, the difference between the action of human and bovine tubercle on rabbits is constant. But this will in no wise deter the clinician observer of resemblances from asserting that these differences are slight differences of blend, and not fundamental differences of kind. Moreover, if the clinician observer of resemblances be attacked for this apparent heterodoxy, he can point to the fact that within the past few weeks the orthodox procedure for differentiating the human from the bovine bacillus in the tubercular diseases of childhood, has in Edinburgh and in Berlin, apparently produced distinctly opposite results (1). But now let us proceed a little further.

This view, that these bacilli are not really different in kind but are simply varieties of the same organism has been upheld by many observers. I need not enter into the literature of this subject extensively, so I will first refer to a very few of the recent articles which have appeared in this connection.

First, there is an article "On the so-called types of the tubercle bacillus," by Dr. Malm, of Christiania, published in *The Journal of Comparative Pathology* for 1912. In this we find the following paragraphs:—

"We must obviously assume that, at first, the originator of tuberculosis, the tubercle bacillus, has been of one and the same species, race, type, or whatever it may be termed. Which species of animal first had the unfortunate distinction of having afforded habitation and nourishment for tubercle bacilli will never be discovered; possibly it was the human race, or possibly some cold-blooded creature, which first adopted and then rendered pathogenic and virulent a saprophytic form of tubercle bacillus. About that it is useless to speculate. This belongs to the archaeology of bacteriology, which hitherto has been entirely unexplored.

But as certain as, for instance, the stumpy and gnarled dwarf birch and the tall luxuriant hanging birch originated from the same seed, or, as the British Commission puts it, as the delicate little lap-dog originated from the same stock as the large, robust St. Bernard, so surely is the tubercle bacillus as regards its origin, botanically and etiologically, one and the same creature wherever it is found. This is evident from its shape, its biology, and its pathological effects.

But as the tubercle bacillus in the course of its existence in the different organisms—a bird, a mammal, a human being, or a cold-blooded creature—is subjected to various influences, in part purely vital and mechanical effects, in part chemical and physical influences, it acquires various peculiarities which render it in some some ways difficult to transfer to another and different soil. It is obviously the same with the tubercle bacillus

(1) See Moller. *Deutsche Medizinische Wochenschrift*, 18th Sept., 1913.

as with other plants; it has to be acclimatized, and varieties are evolved on account of variations of soil and temperature and other circumstances. And the greater differences in the soil the more difficult the transplantation.

Therefore at present there cannot be properly defined differences between more than three varieties of the tubercle bacillus, viz., those of mammals, of birds, and of cold-blooded animals, respectively. Even if from experiments it appears possible that transformation from the one race or type into the other of these three may occur, and even if it seems that spontaneous representatives of bird bacilli may be found in mammals, mostly in swine, yet the examinations hitherto made appear to prove that in practical life bird bacilli and fish bacilli do not play any part as regards human tuberculosis, without, however, our being able to disregard these forms entirely.

In the mammalian race, on the other hand, the tubercle bacillus is one from an etiological and epidemiological point of view, and the bacillus can be equally dangerous whether it is descended from a human being or from another mammal."

Later on he goes a little further, for he says (page 215):—

"As regards the length of time necessary to produce in a bacillus of the one kind the properties of another race there is, of course, no fixed rule. Circumstances and the difference between the soils play here a large part. But in some instances it seems as if it does not take so very long to produce a variation in the hereditary peculiarities of a tubercle bacillus. To create a human type from a bird type, or from a fish type, or *vice versa*, appears to be difficult, and it is in actual life doubtless of very rare occurrence. But Nocard succeeded in the course of five months in one instance, and of eight months in another, in transforming a human and a bovine tubercle bacillus into a bird bacillus by introducing a cell (capsule) with tubercular bacillus into the pectoral cavity of a bird. Moeller has in the course of a year transformed a human tubercle bacillus in such wise that it grew as a fish bacillus; and Klimmer in the course of about nine months rendered human bacilli non-virulent by passing them through a salamander. Dubard's fish bacilli are also descended from human bacilli, as his carp in the course of a year were fed with human bacilli. I myself have fed carp from the lake Maridalsvand (near Christiania) with human bacilli for several months, but on opening the carp no bacilli were found."

But there are other observers whose types of mind for seeing resemblances are more keen than this, and of such probably Ferrar (2), of Barcelona, is as good an example as can be cited.

As he puts it: "The current dogma runs to the effect that the acid-fast bacillus of Koch is the causal agent of tuberculosis, and that the tubercle itself is the anatomico-pathological "basis" of the disease. "This dogma," quoth Ferrar, "which is generally held to be indisputable, expresses but a half of the whole truth." He does not deny that Koch's acid-fast bacillus has the properties and behaviour, under certain natural conditions, that we observe distinguish it in the laboratory. But he does aver that the knowledge we possess of the behaviour and properties of the organism under the strictly confined conditions of the laboratory does not justify us in declaring that, under natural conditions, it always behaves in the same way, and manifests the same distinguishing characteristics. He goes further still, and attempts to reveal to us the natural history of the organism in what he considers its different phases. The

classical tuberculosis of the clinician is, to Ferrar, but the last stage of a complex process that, in its inception, is a more or less acute affair, without "anatomical signature" and in which Koch's bacillus, as we know it, plays no part. His conception is that, in the beginning, there is a "bacillosis" of the lymphatic system, with a consequent destruction of erythrocytes and resultant phenomena of a toxic nature. Later on the liver, spleen, lung, and other organs become the seats of "banal" inflammatory processes, which apparently subside and are cured spontaneously.

Clinically, we do not nowadays recognise the connection between these inflammations and catarrhs on the one hand, and tuberculosis on the other. But in by-gone days they were, with real justice, hailed as evidences of "pretuberculous" processes. The provoking agent of these pretuberculous inflammation is, in Ferrar's view, a saprophytic "ancestor" of Koch's bacillus; not acid-fast and easy of cultivation. But, just as this saprophytic organism modifies the host, so itself does it become adapted to its new environment. It loses its readiness for cultivation; it becomes an obligatory parasite; once an organism capable of rapidly causing death by setting up non-specific inflammatory and toxic processes, now it obtains as the producer of specific chronic tuberculosis: ultimately developing acid-fast properties. Before it passes into the latest and conventional stage of being an acid-fast and obligatory parasite, it exists for some time in the body as a *tuberculinigenous*, but non-acid-fast and yet obligatory parasite."

Along with this let me refer to a paper by Much, quoted in *The British Journal of Tuberculosis*, for April, 1913 (3). "Much attaches great importance to the position of the tubercle bacillus in the system of acid-fast bacteria. The acid-fast organisms are in a class by themselves, and display certain well marked biological relationship with each other. Deycke succeeded in producing a specific reaction in tuberculous subjects and lepers with a fatty substance derived from a non-pathogenic saprophyte. It was further found that a fatty substance derived from the tubercle bacillus gave the same specific reaction with lepers and with tuberculous subjects as the fatty substance derived from the saprophyte. It was then proved that the reaction capacity of acid-fast pathogenic organisms extended still further, for the specific anti-bodies of infected persons gave specific reactions with acid-fast species that were non-pathogenic. Tuberculin and bacillary emulsions derived from leprosy, smegma, timothy grass, and blind-worm were used. The reactions showed a regular scale of gradations in perfect accord with the degree of relationship existing between the tubercle bacillus and the other organisms."

But as regards our view as to the mutability of the tubercle bacillus, even more cogent information is contained in an article on John's disease by M'Fadyean, Sheather, and Edwards, in the volume of *The Journal of Comparative Pathology* (4) already referred to. In this article reference is made to Twort's work, in cultivating the lepra bacillus of man and also the John's bacillus in media to which the ground up bodies of dead human tubercle bacilli had been added, and also to his having found that the addition of dead timothy grass bacilli to the medium had given better results than had the addition of human tubercle bacilli. M'Fadyean and his co-workers also point out that Twort and Ingram had obtained little or no growth on media with which the avian bacillus had been incorporated, and entirely negative results when bovine bacilli were employed. M'Fadyean and his co-workers, however, found that the

(2) See *The Universal Medical Record*, April, 1913, for Ferrar's article in the *Archives General de Medicine*, January, 1913.

(3) *British Journal of Tuberculosis*, April, 1913, page 115.

(4) *Journal of Comparative Pathology*, Vol. xxv., 1912.

avian bacilli generally acted best, and that they got rather better results with human bacilli than with timothy grass. They also emphatically state that in contradiction to Twort's finding, in their experience the bovine bacillus was as useful for the growth of Johne's bacillus as was the human. But a further very interesting statement which they make is that in animals suffering from Johne's disease, they, on testing them in the ordinary way, obtained reactions in certain cases with both avian and human tuberculin.

The conclusion from all this to which the clinician type of mind will arrive is that his own view as to the mutability of these organisms is all the more likely to be the correct one, and further, that in coming to conclusions as regards those organisms and their relationships to disease we had best regard them in the way which will give us the widest horizon.

Next let me draw your attention to the question of the mutability of those organisms looked at more from the clinical side. You all know of the cutaneous tuberculin reactions, the so-called "Von Pirquet" test. Some information on this may possibly be of use.

Of 116 cases of phthisis tested recently with human tuberculin, 84, or roughly 72 per cent gave a positive reaction, and 32, or 28 per cent, a negative.

But dividing those cases into three classes, A, B, and C, and classing in the A's the favourable cases in the B's, the possibly favourable cases, and in the C's the most probably unfavourable cases, this Pirquet test gives further interesting information. In the first place, it is found that among the advanced and unfavourable cases the reaction is not so frequent as among the early. Thus, among C's the positive reactions occurred only in 66 per cent, while among the B's they numbered 77, and among the A's 75 per cent.

But another point is that if we divide the positive reactions in A's, B's, and C's, into marked and moderate or slight reactions, we find that whilst among the B's, and even still more among the A's, the marked reactions distinctly outnumbered the slight, yet among the C's, the reverse as regards strength of reaction was met with.

In this way, whilst experience is making us recognise the limitations of this cutaneous reaction test as a diagnostic, yet we know that it must mean something, and may be to some extent of prognostic use. To me a marked reaction often presents itself as a favourable rather than an unfavourable sign, it means, at any rate, some reaction power. As every physician knows, the most grave cases of lung tubercle, are often those in which there is no fever, i.e. no evidence of reaction for months.

But now let me tell you the results of this cutaneous test with bovine tuberculin.

Of those 116 cases tested with bovine tuberculin, 72, or roughly 62 per cent., were positive, and 44, or roughly 37 per cent., negative. Dividing them again into the classes A, B, and C., we find that among the advanced cases the reaction is not so frequent as among the earlier. Our figures show amongst the C's, positive reactions are only 50 per cent., whilst amongst the B's, they numbered 75 per cent., and among the A's, 50 per cent. Dividing again the positive reactions into marked, and moderate or slight reactions, we find, though to a much less extent, a preponderance of marked reactions again show among the more favourable cases. It would seem then that bovine tuberculin acts like human tuberculin, but to a less marked extent—that is to say, that bovine tuberculin acts very much like somewhat diluted human tuberculin. We have tried also those cutaneous reactions with many other fluids, serums and vaccines, but amongst these I would specially mention sterilised cultures of the timothy and of the smegma bacilli. I cannot as yet give you any figures, but I have no hesitation in saying that with timothy and smegma the

difference between their reactions and those of the human and bovine tuberculins is mainly one of much less strength.

But now whilst acceptance of this view of the mutability of these bacilli entails recognition, that between so-called non-tuberculous and the tuberculous persons there is no real dividing line, it entails also the belief that the degree of virulence of tubercle bacilli must vary in individual cases of tubercular disease. That this is so is borne out by the findings of the Royal Commission previously referred to, but to discover if any information on the subject could be obtained clinically we investigated as follows:

Taking two cases of phthisis, say A. and B. A. advanced and acute, B. early and mild—we made sterilised cultures of their sputum, and employed these for the cutaneous reaction test, in them and in other individuals mostly healthy. Curiously, we found that whilst A. reacted better with B's culture than with his own, and B. with A's than with his own, amongst the other individuals on whom we tried it, some reacted with A's, and some with B's, in a way which seemed inexplicable. All that we could say, therefore, in conclusion to this, was that although there might be differences in the virulence of the bacilli in any two cases, yet these differences were not more than could be counter-balanced by differences in the skin nutrition power of the various individuals tested.

And now, gentlemen, this paper must shortly come to a conclusion, and so as one who believes implicitly in this mutability of bacilli, and as one who is anxious to induce you all to believe in it as well, I shall leave the consideration of those experimental and culture investigations, and endeavour to put before you as concisely as I can, the ideas on this subject which, after 35 years of work at the interpretation of diseases, I have felt myself compelled to form.

I have already mentioned to you the comparison which has been made of different types of bacilli with different breeds of the dog tribe. In this connection I can easily understand how the bacteriologist, with his type of mind best fitted to see differences, may say—"When the clinician can show me a pair of toy terriers produce a St. Bernard dog, then I'll believe that an innocuous and useful timothy or smegma bacillus can become an active and virulent tubercle bacillus." To this, however, I would reply that such is not the problem. Apart from the untraversable gulf between bacilli and dogs, as regards the times and environments required for such a metamorphosis, the problem is a different one. The problem is really the transformation of a harmless and beneficent organism into a harmful and maleficent one, and if the laboratory worker only looks he will see, not perhaps every day, but certainly several times every year, instances of such transformations among things much higher than bacilli, for he will see instances of most useful and beneficent collie dogs becoming transformed into most destructive and maleficent sheep worriers. Not only this, but he will, if he likes, see or hear of instances where these destructive and maleficent dogs have by contact infected others of their own kind.

Now for what causes the transformation of the valuable and protecting collie into the harmful and destructive sheep worrier, we have a simple and scientific explanation. Remembering that in evolution of the species a wolf-like animal has been the ancestor of the dog, we say that this is simply an example of a reversion in the individual animal from the modern civilized to the ancestral savage type; a reversion brought on, we cannot precisely say how, but probably by something faulty in its environment and handling, through its heredity.

It is a big change to turn from the highly evolved dog to the simple bacillus, but between them we can

recognise some all-important analogies. In the first place we have to remember that the functions of life, the nutrition of the individual and the reproduction of the species are the same in all living beings, high and low. In the second place we have to remember that bacilli, like other living beings high and low, in the various and ever changing habitats, and environments through which in successive generations they passed their life histories, must for some periods live lives during which their activities are controlled and limited, and at other periods live lives in which these enjoy luxuriant freedom. It appears to me to be only in consonance with the harmony of nature to believe that the broad general conditions which govern the transformation of the useful collie into the destructive sheep worrier, and of the harmless germ into the virulent tubercle bacillus, are one and the same, viz., a faulty environment or handling, induced in the progress of civilization by the actions and reactions between them and an ignorant, blundering, selfish humanity.

Take, for example, the cow. Probably in some of its secretions, at any rate, through the grasses which it eats, bacilli, acid-fast or not, are to be found constantly present in its body. As long, however, as the cow is allowed to lead a natural life, in natural surroundings, all is well. Milk, however, is one of the needs of mankind, and with the progress of civilisation and the crowding of people in towns, it is needed in larger and larger quantities. Moreover, the people demand it at the lowest price at which they can procure it, and the dairyman has to make his livelihood. The result is that as regards environment and handling, that is to say as regards exercise, fresh air, sunlight, temperature, kind of food, etc., this cow tends to be so placed that whilst living so as to give the maximum quantity of milk, it is living in exactly the conditions which, by impairing its health and resistance power, favour the transformation of innocuous or useful organisms into virulent ones. But, further, as regards heredity. Bearing in mind the great natural law of the antagonism between nutrition and reproduction, and bearing in mind the fact that milk-giving for the community means the excessive cultivation of the reproductive activities, the breed of cow which the dairyman tends more and more to select, so as best to meet the demands of the community for quality and cheapness, will tend generation after generation to become less and less efficient from the nutritive point of view. That is to say, its tissue nutrition power must become less and less capable of preventing virulent transformations in these bacilli, and less and less capable of resisting their ravages when these transformations are complete (5).

I need not in your presence speak of the dangers of tubercle infected milk, but it must be evident that the remedy must be, not alone the killing off of affected animals, but improvement in all the conditions in which these animals are permitted to live. Indeed, when we reflect that milk is not a food only, but is in addition and in reality an animal secretion, it will suggest to us that the milk from cows not tuberculous, but merely living under the conditions which give the germs within them their tuberculous virulence, cannot but be a source of danger. The belief that this is so must, for its acceptance, appeal to common-sense and knowledge, but the statements of Courmont and Cade (6) that agglutinins can be transferred to an infant through the milk of a wet nurse, and of Salge (7) that diphtheria antitoxin may be so transmitted and absorbed by the infant, seem to afford it a scientific corroboration.

(5) For an interesting article on this subject and on milk records see Watson on Tuberculosis. *Scottish Farmer*, Nov. 19th, 1910.

(6, 7) See "Serums, Vaccines, and Toxins," by Bosaquet and Eyre. 2nd Edition, 1909.

I need not discuss with you the subject of the transmission of tubercular disease from bovine to bovine, nor need I enter into a consideration of how in the human subject virulent bacilli may be developed from non-virulent ones when the conditions of life are rendered unhealthy. My object has been to-day to lay before you the subject of the mutability of bacilli—human, bovine, or whatever they may be, and I cordially trust that what I have said may lead you to devote to this subject the careful consideration which I, for one, feel that it most emphatically deserves.

DISCUSSION.

Following Prof. James' lecture there was a discussion which was taken part in by Profs. Dewar, Gorton, and Matheson, and Messrs. Riddoch and Storie.

Mr. Riddoch, in thanking Prof. James for his lecture, said: We are exceedingly obliged to Dr. James for coming here and giving us such an instructive lecture this afternoon. I do not believe that disease organisms were created disease organisms at first, but finding themselves by accident or otherwise planted in animal tissues they endeavour to become accustomed to their surroundings—their environment, and if the vitality of the animal was lowered they of course gained the ascendancy. The whole subject is of considerable importance, and the meeting is now open for discussion if anyone has any remarks to make on the subject.

Mr. STORIE: I wish to say how much we are indebted to Dr. James for his very excellent paper which he has read to us to-day. I am sure that from his great experience in working with the tubercle bacilli his opinion must bear great weight. He has opened perhaps one of the very widest subjects he could possibly have taken up with regard to bacteria. It appears to me that it is principally a matter of evolution of the bacteria and nothing else. What we understand as this tubercle bacillus may perhaps be the most adaptable of all living organisms; it can adapt itself to more extraordinary circumstances than perhaps any other living organism we are aware of. The burning plains of India and the Polar regions are quite the same to it. All animals, from the warm-blooded mammals to the cold-blooded fish are quite the same to it, and we must see, when considering these things, what a scope there is for this evolution and mutability. I have listened with great interest to this paper, more especially as I have thought a great deal on the subject myself. I feel much indebted to Dr. James, and I am sure it will give us all food for reflection for many a long day.

Professor DEWAR: I do not need to say anything. I listened with very great pleasure to my friend and colleague, Dr. James. This paper will make us think. I find that Dr. James is still the old Dr. James. He does different things for himself, he causes us to think, too, I have not the least doubt. I know that there are differences in the virulence of the tubercle bacillus. I know I have seen tubercle existing in a herd, over which I have had control, for years, and not doing very much harm, and a new animal perhaps introduced as a different type—a different strain, if you will—evidently a tubercle which propagated itself and the contagion to others of the herd very rapidly. I have no doubt that where there can be mutability there are differences in the virulence of strains of bacillus. It is a big subject, we could argue on it for weeks. (Laughter.)

Professor GORTON: I am sure that, though Dr. James' paper contains rather too much for one to absorb in the short time, he has taken up a very big question, and one I would not like to attempt to discuss at present without having the opportunity of reading and studying it. I have been extremely interested in listening to Dr. James' remarks, because of the fact that the views he has placed before us have been so far from the orthodox views. It does us a very great deal of good to have it

brought so forcibly in front of us that there are at least two views on any question. I would venture just to touch on the paper. I have been able to follow some of his arguments, and on the remarks he has drawn certain conclusions, but with regard to others I must confess I have not been able to follow him, and I must say I have felt, rightly or wrongly, that some of the analogies he has drawn are just rather too wide—certainly wider than I am able to appreciate. I cannot quite follow the significance of his analogies in some instances. I wish to express my extreme pleasure in having the opportunity of listening to his paper, and the expression of his views. (Applause.)

Professor JAMES, replying to the discussion, said: I want to express my great pleasure in coming here and finding myself among you. This subject is a great, big, broad one, and my object was rather, what I find myself doing every day, to impress upon my neighbours that our knowledge is not finite—that we are in a state of transition regarding knowledge. The tendency of late times has been far too much to believe that things are settled and done with and cannot be controverted. I wanted to stimulate the optimistic spirit if I could. It is for this reason that I took up this question of mutability. One's time is limited, and this subject, which you and I have in hand, I thought might interest you. I can only express to you my great thanks for allowing me to come here and for the patience and attention given to me to-day. (Applause.)

Mr. RIDDOCH: We are extremely grateful to Dr. James for giving us such an interesting paper, and I propose that we give him a hearty vote of thanks. (Applause.)

SPLIT PASTEREN.

Mr. STORIE submitted a specimen of a split pastern. He said: The symptoms at first were very like foot lameness. Pressing the back of the foot was the only way we could get the animal to evince any pain. In a few days the lameness had increased, and in three or four days you could get a little pain by twisting the toe. However, the animal became very lame, and it was destroyed.

FRACTURE OF INNOMINATE—REPAIR.

Mr. PEGGIE exhibited an innominate bone showing a wonderful, though imperfect, repair of a fracture, and gave the following description of the case: "Two months ago I was called to see a carriage mare, 16 years old, with the history that she had come in lame the night before. The gentleman, who was driving the pair at the time, was coming down a slight incline at the walk, when the mare suddenly "huffed" herself, and immediately hopped off on three legs. As he had only about a quarter of a mile to the house, he trotted her home. The groom hosed the fetlock with cold water, and applied some concoction to the abrasion, thinking that the mare was lame from that cause; but as she was no better next morning I was consulted. When I arrived I found her sweating a little, temperature 102° F., and showing, when she walked, marked symptoms of hip lameness. Nothing could be seen or felt on external manipulation, but when the leg was lifted and abducted, she evinced signs of pain. I examined her per rectum and came to the conclusion there was a fracture of the body of the ischium. I informed the owner, who was very surprised and, in fact, questioned the diagnosis. He said he would like her treated, as she was a favourite. A dose of physic was given, and a strong mixed blister placed over the affected region, and a "wait and see" prognosis taken up. She was not put in slings, as she was of rather a nervous disposition. After the blister had been on for about six weeks I had her taken out of the box, and tried her at the walk, and was pleased to find her walking fairly sound. I therefore advised that she should have a run

at the grass. Accordingly the mare was turned out. The owner, however, became impatient, and had her taken up, after having been only two weeks out. I now examined her again, and found she could walk and trot surprisingly well, and showed very little pain on extreme abduction of the affected (near) leg. I may say this animal was insured, and the insurance company instructed Professor Dewar to make an examination of her. Per rectum the Professor also diagnosed fracture, and endorsed my treatment. Unfortunately the mare, after doing so well, died from twist of the large bowel nine weeks after her accident. On post-mortem examination, I found, as you will see from this specimen a double fracture: first of the shaft of the ischium, and second of the pubis. I may say no swelling was ever seen in the mammary region. I think the case is of interest, first, from the obscure cause of the accident, also from the slight nature of the lameness, considering the grave nature of the injury, and also from having so perfect a bony union in two months' time in such an aged animal.

JAMES HENDERSON, Hon. Sec.

NORTH WALES VETERINARY SOCIETY.

The annual meeting was held at the Mona Hotel, Carnarvon, on Tuesday, September 9th, 1913. The following members were present: Messrs. Frank Booth, Colwyn Bay, President; Richard Jones, Towyn, Hon. Treasurer; Hugh Williams, Ty Croes, Vice-President; R. S. Rowlands, Abergele; C. W. Cartwright, Dyserth; Wm. Hughes, Caerwys; O. Trevor Williams, Llangefni, John Mathews, Llanfair, P.G.; Owen Thomas, Llanerchymedd; L. W. Wynn-Lloyd, Hon. Sec.; and Jas. Smith, Llandudno, visitor.

Apology for non-attendance was received from Dr. Evans, M.R.C.V.S., Bangor.

The minutes of the previous meeting having been read, Mr. Trevor Williams proposed, and the Hon. Sec. seconded, that the annual subscription be reduced from 10/6. to 5/-. Carried.

ELECTION OF OFFICERS.

President.—Mr. Hugh Williams, Ty Croes.

Vice-President.—Mr. Wm. Hughes, Caerwys.

The Hon. Treasurer and Hon. Secretary were re-elected.

The President gave a brief *résumé* of the working of the Tuberculosis Order (1913), and discussed the proposed Milk and Dairies, and Anaesthetics Bills.

The meeting terminated with a hearty vote of thanks to the retiring President.

After tea the members witnessed two operations on cases provided by the Hon. Sec.; one of scirrhus cord, operated upon by the Hon. Treasurer; and another of umbilical hernia, by Mr. Trevor Williams, by means of Malloch's aluminium clam.

It will interest the members to know the progress of these cases. The case of scirrhus cord was discharged in four days, and made an excellent recovery.

The one of hernia was seen daily, the clam tightened, and the part dressed with an antiseptic solution. As we had attended a case of tetanus on the farm last year, we injected a dose of anti-tetanic serum on September 6th as a precaution. On the 23rd we went to remove the clam, and were surprised to find that tetanus had set in. The clam was removed and serum injected daily for eleven days. K.I. was given in the drinking water, and Pot. brom. C. Chloral hydras in the form of electuary. He was taken out for exercise on October 14th, and has since maintained good progress. I might add that the operation was a complete success.

L. W. WYNN-LLOYD, Hon. Sec.

DISEASES OF ANIMALS ACTS, 1894 TO 1911.

Return showing the number of Premises on which the existence of TUBERCULOSIS has been notified to the Board of Agriculture and Fisheries during the month of October, 1913.

* Number of bovine animals suffering from tuberculosis of the udder, tuberculosis with emaciation, or giving tuberculous milk, in respect of which notice of intention to slaughter has been received.

The Tuberculosis (Animals) Committee.

A meeting was held on 22nd ult., in London. The Earl of Northbrook, who presided, explained that as the outcome of a meeting of the Committee held in April last, he had written a letter to the Board of Agriculture making certain recommendations, and stating that the Committee were apprehensive that in its present form the Tuberculosis Order would inflict some hardship upon many owners of cows which were apparently healthy. It had recently been suggested to him that the time had arrived when the Committee might meet to consider the working of the Order, which had been in operation since May 1st. For the assistance of the Committee he had sent a communication to every County Council in Great Britain, asking for detailed information as to the administration of the Order, and up to the present date some fifty replies had been received.

It was resolved that the Committee be adjourned until a date to be fixed by the Chairman, and that in the meantime the information obtained from the various counties be printed and circulated to the members of the Committee.

THE LATE WM. HUNTING AND HIS INFLUENCE ON VETERINARY SCIENCE.

"For some we loved, the loveliest and the best
That from his Vintage rolling Time has prest,
Have drunk their Cup a Round or two before,
And one by one crept silently to rest."

The history of the profession shows that from time to time there were certain members who, by their researches, observations, devotion to work, example and personality, exerted a remarkable influence in the direction of progress. In the earlier days progress was achieved by the clinician; no doubt it was slow, for he had to depend on his unaided efforts to discover more successful methods of diagnosis and treatment; moreover, there were prejudices to overcome, and the duties to be performed left little time for investigation. Later on, with the advent of pathology, and physiology, and more precise methods of diagnosis, the opportunities for progress were more numerous, the number of workers increased, and preventive medicine commenced to occupy an important position. Slowly, but surely, the profession has advanced, until at the present day it has reached a position far beyond the expectations of its most enthusiastic pioneers. But it must not be forgotten that all this progress and advancement is the work of individuals, that it required devotion to duty, an iron will, self-sacrifice, and an enthusiastic spirit. Moreover, in addition to these attributes, personality and example were necessary in order to attract and lead others to commence and to carry on the laudable ambition of raising the profession to its highest level, of increasing its utility, and improving its literature.

Amongst the long roll of those who have exerted a marked influence on the progress of veterinary science, the name of William Hunting will ever remain pre-eminent. Richly endowed with all the attributes and qualities mentioned above, he has shed lustre on our calling, and his career is an example which many will, no doubt, emulate, but few will succeed in truly following. His additions to veterinary literature are too well known to need comment, and his inducement to others to publish their observations and experience has resulted in a vast accumulation of valuable material in the volumes of *The Veterinary Record*.
